Value of Succinylcholine Chloride in Electroconvulsive Therapy

BURTRUM C. SCHIELE, M.D., and PHILIP M. MARGOLIS, M.D.
Minneapolis, Minnesota

IN RECENT months succinylcholine chloride (Anectine*) has become established as the most practical and valuable muscle relaxant for use with electroconvulsive treatment (E.C.T.). Every physician who uses electroconvulsive therapy should familiarize himself with this drug and be able to use it if the occasion demands, though he may or may not wish to adopt it as a routine procedure. One never knows when he will encounter one of those desperate situations when urgently needed electroconvulsive therapy is contra-indicated by some physical abnormality (e.g.—an acutely distributed patient with a fresh fracture). The purpose of this paper is to report on our experience and to outline a variety of techniques for use under varying circumstances.

Succinylcholine chloride is a white crystalline water-soluble solid made up of two molecules of acetylcholine chloride linked together at the alpha methyl groups. When injected intravenously, it rapidly produces voluntary muscle relaxation or flaccid paralysis. It acts at the motor end plate, as does acetylcholine, blocking myoneural conduction; this action is of short duration (one-half to three minutes) as the drug is rapidly hydrolyzed into the normal metabolic products of choline and succinic acid. The flaccidity develops in an order similar to that with curare, viz: (a) eyelids, (b) face, (c) extremities, (d) back, (e) intercostals, (f) diaphragm. Disappearance of the paralysis is in the reverse order. It is possible to give electroconvulsive therapy with the patient so completely paralyzed that almost no muscle movement occurs.[3]

Following E.C.T., the average patient usually begins to breathe promptly—as if no succinylcholine had been used. However, prolonged apnea (three to twenty minutes) may occur in unusual cases. There is no known antidote; prostigmine is contra-indicated. Artificial respiration by manual chest compression is insufficient in such cases of prolonged apnea. Because of this possibility, one should not use succinylcholine chloride unless he is skilled in the administration of oxygen with a positive pressure mask.

The mechanism of prolonged apnea is not completely understood. There is some evidence that the cholinesterase of the plasma may play a part. Bourne and Evans[2,4,5] observed that eight patients with delayed recovery showed a low plasma cholinesterase level, suggesting that caution be used in patients with liver damage. As an added safety precaution it may be advisable to have a suction apparatus, airway, and intubation tray available. If the physician is inexperienced or the patient's condition warrants it, an anesthesiologist could be called to assist in the first few treatments.

There may be minor but definite side effects and after effects. When the drug is given rapidly, the paralysis is often preceded by a transient stimulatory phase, involving some muscle twitchings. Murray[9] reported chest soreness, burning in the throat, and pain in the jaw and back of the neck as the three occasional complaints of his patients. He injected himself with 20 mgm. of succinylcholine chloride and confirmed the above symptomatology referred to by his patients. The pain and burning diminished gradually over a

*There are other drugs such as succinylcholine iodide which are reported to have essentially the same physiological action, but we have had experience only with the succinylcholine chloride. ('Anectine' is the Burroughs Wellcome and Company brand name.)

102031

period of twelve hours. On the other hand Mayrhofer[7] gave himself a series of injections and experienced no side effects whatsoever.

As far as the evidence indicates at the present time, succinylcholine chloride has no observable detrimental effects on the cardiac status. Nowill, Wilson and Borders[10] report some changes in electrocardiogram, blood pressure, and pulse recordings, which were however all transient (less than three minutes) and partially eradicated by the proper dosages of atropine sulfate (gr. 1/75 or higher) administered before the treatment. As a result succinylcholine chloride has been proposed as the drug of choice for cases with increased cardiac risk. In such cases we may use bag and mask controlled respirations with high oxygen concentrations before and/or after electroconvulsive therapy.

There are several possible techniques of administration. Most writers[1,6,8,11] advocate succinylcholine chloride-sodium pentothal mixtures. Murray[9] advocates the use of succinylcholine chloride alone, feeling that the addition of sodium pentothal needlessly complicates the treatment procedure.

The basic technique of the current University Hospitals plan involves the use of succinylcholine chloride by itself. This is modified as the need arises, as will be described later. As usual the patient gets no breakfast. Atropine, gr. 1/75 (0.8 mgm.) is given hypodermically thirty minutes before treatment. Everything is made ready before the injection of succinylcholine; that is, head band and mouth protector are in place, and the shock machine is warmed up and set. We place no roll under the patient's back, nor do we hold him.

With this technique the time factor is critical if the patient is to be spared unpleasant sensations. We inject the succinylcholine chloride rapidly intravenously; that is, in about three to five seconds. Verbal reassurance is given to the patient during the few seconds that it takes the drug to act. For example, he may be told that he will feel the medicine beginning to take effect but that he will be asleep very soon. Twenty-five seconds to thirty seconds after termination of the injection, the treatment is given. The hand-grip disorganization sign employed by Murray[9] had not been consistently reliable in our experience.

Ten mgm. (0.5 cc.) is the usual initial dosage. If this fails to produce adequate relaxation, the dosage of subsequent treatments is increased. We have seldom found it necessary to go beyond the 20 mgm. level. Once the dose is established for a given patient it has been found to remain constant.

Modifications of the basic technique are sometimes utilized. If a patient is fearful before the treatment or restless after it, sodium amytal, gr. iii orally one hour beforehand, is helpful. If this is insufficient and especially if the patient is markedly upset or complains strongly of muscle twitchings and/or smothering sensations, intravenous pentothal is used instead. Sufficient pentothal (from 50 to 200 mgm.) is injected to make the patient drowsy; this is followed by administration of succinylcholine chloride via the same needle but from a different syringe; then forty-five to sixty seconds later, the treatment is given. Some clinicians[6] employ succinylcholine chloride-pentothal mixtures in the same syringe. This method may work if the mixture is administered at once. However, since succinylcholine chloride hydrolyzes rapidly when mixed with pentothal, the technique would appear unreliable, as the effective amount of succinylcholine which actually reaches the patient will be unknown and variable.

During the period from July 1, 1953 to June 30, 1954, we have treated 114 patients with a total of 957 electroconvulsive treatments. A breakdown of the 957 treatments revealed the following:

137—Treatments with sodium pentothal alone. Of these 130 were given during the first part of our 12-month period. Later when the staff had become impressed with the value of succinylcholine, almost everyone was given its benefit.

667—Treatments with succinylcholine chloride alone. In 23 treatments the patient was given sodium amytal, gr. iii, orally one hour beforehand.

110—Treatments with succinylcholine chloride and sodium pentothal in combination.

43—Treatments with no medication.

Since we are stressing the role of succinylcholine chloride in this report, we shall discuss our findings on the bases of (1) complaints of the patient concerning the immediate effect of the drug; (2) post-treatment complaints, and (3) degree of modification of the grand mal seizure.

1. In about one-quarter of the treatments, there were complaints relative to the immediate effect of succinylcholine just before the administration of electroconvulsive therapy. Of those who

had complaints, about half voiced them immediately; the other half told us about them later in the day, that is, they remembered well how they had felt. Most of these complaints were minor, consisting of vague "discomfort," mild restlessness and moderate anxiety. Several patients on one or more occasions revealed considerable apprehension, spoke of twitchings of the muscles (especially of the face) and smothering sensations. One patient in describing her distress said, "I couldn't breathe: I wanted to talk and scream but I couldn't." About 80 per cent of these latter difficulties were resolved, either by sodium amytal orally beforehand or by the use of a pentothal-succinylcholine combination. The above complaints were more numerous during the first few months of our experience. As our technique improved and as our staff gained confidence, the complaints occurred less and less frequently.

2. Probably most patients who receive E.C.T. suffer from some degree of post-treatment discomfort such as headache, nausea, occasional vomiting. These complaints occurred in many of our patients irrespective of the type of medication used. In addition to the above, several patients had complaints which appeared to stem from the use of succinylcholine chloride: (a) dryness of the throat, (b) pain in the neck, chest, and back, and (c) jaw and calf pain. Patients who did not receive succinylcholine chloride did not complain of these symptoms. These complaints persisted with decreasing severity for only a few hours. They were seldom mentioned spontaneously but could be elicited by questioning after about 15 per cent of the treatments.

3. Modifications of the grand mal seizures were arbitrarily divided into the classifications good, fair, poor or none. We considered the modification to be good if there was very little tonic and clonic reaction. We did not feel it was necessary that the convulsive seizure be completely eliminated as would be possible with this drug. If the patient had only slight modification the reaction was classified as poor. On a dosage of 10 mgm. a trifle more than half of the treatments fell into the fair or poor categories; but when the dosage was raised to 15 or 20 mgm., 80 per cent of the modifications were good and 15 per cent were fair. In two cases, when intravenous pentothal was used in combination, it was necessary to raise the dose of succinylcholine (once up to 25 mgm.) to obtain a satisfactory modification of seizure. The succinylcholine had no apparent effect whatsoever in two other cases in spite of 20 and 25 mgm. doses. We did not go higher. Once a satisfactory dosage was obtained for a given patient, we found this to produce a constant effect. There was one exception—in this patient for some unknown reason the same dosage brought different responses on different days.

It is not part of our routine to obtain spine x-rays before E.C.T., and we take post-shock x-rays only if the patient has physical complaints referable to a possible skeletal injury. In the above-reported cases, there was no clinical evidence of fractures or dislocations. X-rays were done in the case of four patients all of whom complained rather markedly of back pain; they were all reported as negative.

We had a few special problems. One female patient was apneic for seven minutes. She had been given 250 mgm. pentothal, followed by 10 mgm. succinylcholine, preceding the E.C.T. She received oxygen via the bag-breathing method until she began breathing again. A second female patient appeared to have recovered satisfactorily but suddenly became apneic in the recovery room at least five minutes after E.C.T. had been administered. She was apneic for two minutes, was not given oxygen, recovered spontaneously. These two patients experienced no difficulties in succeeding treatments. The first treatment of another female patient, utilizing 10 mgm. succinylcholine, produced a complaint of severe pain in the neck with muscle spasm, necessitating cessation of therapy for ten days. Treatments were then resumed with 15 mgm. succinylcholine without further difficulty. Whether or not this was related to the succinylcholine, or even to the E.C.T., is open to question.

It is of some interest to note that the patient who had the greatest difficulty in this series was one who received no succinylcholine but rather pentothal alone (150 mgm.). He was apneic for 10 minutes and suffered severe laryngospasm. He was breathed by the bag method until he took over control himself. Subsequent treatments without any medication led to mild laryngospasm but much less severe in nature.

It would be well to mention that the use of succinylcholine chloride did not appear to influence the therapeutic effect of E.C.T. in any way.

Summary

Succinylcholine chloride has proven to be an ideal muscle relaxant for routine use with electroconvulsive treatment. Because of its rapid but short-lived action, it is far superior to most other drugs. Its use allows the physician to administer electroconvulsive therapy to a larger variety of patients than heretofore; aged persons, those with orthopedic complications, and cardiac cases, can be treated with less risk.

We have described our treatment procedures: as a routine, we have found it safer and simpler to give succinylcholine alone. This is satisfactory in the majority of cases. For those patients who are unduly fearful or anxious, the procedure may be modified by the use of a barbiturate. Because of the occasional occurrence of prolonged apnea, a positive pressure oxygen apparatus must be available.

Although the patients occasionally complain of certain side effects, we wish to stress that these are minor in nature. They occurred much less frequently as we gained experience and our technique smoothed out.

With a dosage of 10 to 25 mgm., we have found succinylcholine to sufficiently modify or eliminate the convulsive reaction in almost everyone. There were two exceptional cases in which it had no effect whatsoever.

NUMBER OF PHYSICIANS REACHES NEW PEAK

A record graduation of 6,861 physicians during the past year by the nation's medical schools has boosted the ratio to an all-time peak of one physician for every 730 persons in the United States. This ratio will be lowered even more in the next few years, as the number of medical graduates is expected to rise due to the continued expansion of the country's medical schools.

Today's physician population has now reached approximately 220,100. The record graduation figures, as released in the 54th annual report on medical education in the United States by the American Medical Association's Council on Medical Education and Hospitals, include the following:

Enrollment of 28,227 is the largest number of medical students in the history of the United States.

Freshman class enrollment of 7,449 also is a record.

More than 76 million dollars was spent during 1953-1954 for new facilities, remodeling or completion of buildings for medical instruction.

Budgets for medical schools during 1954-1955 total more than 143 million dollars.

A total of 21,328 physicians did volunteer teaching without pay during the year.

Ten new four-year schools are in construction or planning stages and will be in operation within the next few years These schools will be at the Universities of California, Mississippi, Miami, Missouri, Florida, West Virginia, Kentucky, North Dakota and Yeshiva University of New York and Seton Hall University. In addition, three other medical schools are being considered.

Hearing Loss in Children

KINSEY M. SIMONTON, M.D.
Rochester, Minnesota

FOR THE past two years the Committee on Conservation of Hearing of the Minnesota State Medical Association has been engaged in formulation of a program which is directed toward preservation of hearing among the people of Minnesota. Five population groups, each of which has somewhat different problems, are being considered. The categories are: (1) children of preschool age, (2) children of school age, (3) adults, (4) hearing loss in industry and (5) hearing loss among the aged.

Initial emphasis is being placed on the children of school age. This group was selected owing to means of locating individuals through the agencies of the public health services and the school systems in our communities. The program for this group is threefold: location of individuals, information to physicians, and information to parents of handicapped children.

For purposes of location the state was divided into seven districts. Each district was assigned to a member of the committee residing in that district. Committee members asked public health agencies and school systems within the individual districts for the names of children with hearing handicap. For purposes of this survey, handicapping loss of hearing was arbitrarily set at a loss of 30 decibels or more in both ears in one or more of the speech frequencies of 500, 1,000 and 2,000 cycles per second. The co-operation given by these agencies has been admirable. The names of 1,106 children have been submitted to the committee. This number is not complete. Facilities for testing are not available in all communities. One district reported by code number only.

Detection

Early detection is the key to successful therapy or rehabilitation of children who have hearing loss. Our therapeutic victories will be confined to those patients whose hearing loss is due to inflammation of the middle ear or to lymphoid hypertrophy in the nasopharynx. The success of therapy depends on achieving remission of the pathologic process before permanent changes occur. The results of rehabilitation programs are less dramatic, but are no less dependent on early recognition of the handicap with early institution of training measures.

The parents are usually the first to suspect impairment of hearing in the young child. The sense of hearing is present at birth. Some newborn infants will respond to a handclap, although response is inconsistent. It is not usual for children to be brought to a physician for evaluation of hearing before the age of one year. Only severe defects of nerve function are detected at early age. Unilateral or partial loss of hearing may escape detection by the parent. Parents are quite likely to be aware of the bilateral partial loss of hearing associated with bilateral inflammation.

The examination of hearing of young children requires patience, skill and equipment. Froeschels and Beebe found that thirty-one of thirty-three newborn infants responded to tests using Urbantschitsch's whistles as the stimulus. Response was usually by acousticopalpebral reflex. No newborns tested responded to tuning forks. The authors attributed this difference to the strong stimulus required to overcome poor middle-ear function in the newborn.

Ewing and Ewing studied children with normal as well as those with defective hearing. They reported that from birth to two months of age percussion sounds elicit reflex response; that between two months and one year the voice becomes the better stimulus; that moderate voice is better than loud or whispered voice; that learned

---

From the Section of Otolaryngology and Rhinology, Mayo Clinic and Foundation. The Mayo Foundation is a part of the Graduate School of the University of Minnesota.

Read at the meeting of the Minnesota Academy of Ophthalmology and Otolaryngology, Duluth, Minnesota, June 7 to 9, 1954, and at the meeting of the Southern Minnesota Medical Association, Winona, Minnesota, September 13, 1954.

responses replace reflex responses at this age; and that children older than one year respond best to the quiet voice. Various toys were used to hold the child's attention and to evaluate response to spoken stimuli. Similar tests were used for children suspected of deafness. Reflex responses were replaced by learned responses at a later age than in children with normal hearing. Residual hearing for loud sounds was determined by reflex response to loud stimuli. The authors concluded that if a child does not respond to voice by the end of one year he is deaf or has some other gross defect; that if he never turns his head toward the voice of a familiar person at three feet he is totally or severely deaf; and that all children more than the age of one year who fail to respond to a loud voice are totally deaf.

Quantitative hearing tests for young children require special equipment. Bordley and associates reported favorable results from the use of the psychogalvanometer. Dix and Hallpike developed another conditioned-reflex test using a "peep show."

Occasionally hearing loss is first noted by teachers after the child attains school age. Poor progress and lack of attention in school may suggest deficient hearing.

The screening type of tests carried out by school and public health organization is responsible for recognition of many children with partial loss of hearing. These tests are of tremendous value. In my experience, errors tend to be in the direction of indicating too great a loss of hearing. This is no doubt largely due to inattention on the part of the child.

Otologic evaluation is the final step in detection. The otologist has the experience in diagnosis necessary to select those children suitable for therapy from the group requiring rehabilitation measures. He also has the special equipment and skill needed for evaluation of the hearing defect and for following the progress of therapeutic efforts. The experience of the otologist in treatment of otic infection is necessary in those patients who fail to respond to usual measures. The otologist is the only physician who is willing to treat chronic infections of the ear. Chronic infections merit his care as soon as they are recognized. Adequate, early treatment of chronic infection may prevent continuing destruction of the sound-conducting mechanism.

Treatment

Diagnosis of the cause of hearing loss is prerequisite to treatment. The conditions which cause hearing loss in children and which are amenable to therapy are occlusions of the external auditory canal by cerumen, inflammation, foreign bodies or atresias, and interference with the function of organs in the tympanic cavity. Reversible causes of middle-ear dysfunction are acute otitis media, serous otitis media, some cases of chronic otitis media, and impaired function of the eustachian tube. Hypertrophy of the lymphoid tissue in the nasopharynx is an important causative factor in lesions of the middle ear. Infections of the nose and tonsils less frequently cause disease of the ear.

Causes of hearing loss in children not amenable to therapy are the end result of middle-ear inflammation and the loss of nerve function. The latter may be congenital in origin owing to heredity, rubella infection in the mother during the first trimester of pregancy, erythroblastosis or syphilis, or acquired, owing to mumps, trauma, meningitis or syphilis.

The outstanding approach to relief of hearing loss in children is management of lymphoid hypertrophy in the nasopharynx. Adenoidectomy is the principal weapon. In order to achieve relief of middle-ear and eustachian-tube dysfunction, adenoidectomy must be done carefully and thoroughly. The philosophy that adenoidectomy is an adjunct procedure secondary in importance to tonsillectomy is untenable. Blind adenoidectomy is to be avoided. It is imperative that the nasopharynx be subjected to painstaking direct visual inspection and that all remaining lymphoid tissue be carefully removed before the operation is completed. The palate retractors of Lothrop and Senturia are effective instruments. Finger palpation is valuable in locating bits of lymphoid tissue high in the nasopharynx. The Kelly direct-vision adenotome is also a valuable instrument. Adequate exposure requires movement of the patient's head to bring all areas of the nasopharynx into view. Sharp alligator biting forceps such as those designed by Meltzer facilitate removal of tissue from the lateral bands. For removal of the main adenoid mass, a series of La Force adenotomes in various sizes is essential. One cannot work efficiently with an instrument either too large or too small for the nasopharynx.

Each surgeon should plan and follow a definite routine in adenoidectomy which assures clean removal of all lymphoid tissue. The final step should be a searching inspection of the surgical field.

Age is not a contraindication to adenoidectomy if sufficient reason exists for doing the operation. The adenoid is not confined in a capsule. Some lymphoid tissue remains after the most painstaking operation; therefore, recurrence may be anticipated when operation is done in very young children. It is well to advise the parents of this possibility, as secondary operation may be necessary a few years later.

Irradiation of the nasopharynx has limited use in treatment of lymphoid hypertrophy. Small residual lymphoid masses may be reduced in size by irradiation although this agent is not satisfactory for removal of larger masses. Irradiation is not a substitute for adenoidectomy.

Finger massage of the nasopharynx has not proved effective for control of lymphoid overgrowth and control of infection.

Acute suppurative otitis media usually responds favorably to the use of antibiotic drugs. The outstanding cause of failure is inadequate dosage of the drug which results in temporary masking of the symptoms followed by recurrence of the disease. An adequate program is one which provides effective concentrations of the drug at the site of the infection for a period of time sufficient to eliminate the infection. Inadequacy may result from small doses, infrequent doses, or discontinuation before the infection has subsided.

Myringotomy, once the principal weapon in treatment of acute otitis media, is no less valuable today. Institution of surgical drainage of the middle ear early in the course of acute suppuration promotes early healing and decreases the possibility of permanent changes in the middle ear. Myringotomy certainly should be done in every instance of delayed resolution of acute otitis media.

Serous otitis media, if repeated or prolonged, may have permanent influence on hearing. Vigorous therapy is indicated. A few patients respond to the use of antihistamine drugs or inflation of the eustachian tube. Direct removal of secretions from the middle ear by myringotomy and suction or by needle puncture is the preferred direct treatment. Treatment of adenoid hypertrophy is of primary importance. Treatment of nasal infection or of allergy is effective in some patients. Mastoidectomy has been advocated for persistent disease. In my experience the results of mastoidectomy have been unsatisfactory.

Chronic otitis media is basically a destructive process. Early evaluation and treatment by an otologist may in some instances arrest the destruction of tissue and avoid further loss of hearing. Treatment by antibiotic drugs administered systemically is unsatisfactory. Local treatments directed toward removal of debris, promotion of free drainage, and control of infection by topical application of effective drugs are useful. Modified radical mastoidectomy effectively eliminates the disease and at the same time preserves hearing in suitable patients.

Other methods of treatment which are of value in prevention of ear disorders which lead to loss of hearing are treatment of nasal disorders, infections, allergies, or obstruction, and immunization against or preventive management of the acute diseases of childhood.

There is no convincing evidence that nerve deafness benefits from vitamin or mineral therapy.

Rehabilitation

Rehabilitation of the hard of hearing is not the province of the physician; however, the physician can be of great service to his patients by advising them of the possibilities, the aims, the methods and the availability of rehabilitation.

Areas in which advice of the physician is of especial value to the patient or his parents are those of the hearing aid, parental instruction, and available school instruction for the handicapped child.

Selection of Hearing Aids

The hearing aid has a single function: to increase the loudness of sounds reaching the ear. The simplest hearing aid is the ear trumpet or speaking tube. The diaphragm-and-rod prosthesis is useful for a limited number of individuals. This system is more adaptable to use by adults than by children. The electric hearing aid has many features which make it the most widely used prosthetic device for the hard of hearing.

The electric hearing aid is a miniature system made up of the component parts of the public address system, microphone, amplifier, power source and speaker. It is essential that all component parts be included in the instrument for practical function. Advertisements for hearing aids without batteries, cords or earpieces are misleading.

Receivers

Persons with conductive deafness and normal nerve function may be fitted with a bone-conduction receiver. The air-conduction receiver is however, more efficient and should be advised unless disease of the middle ear or canal interferes with wearing the insert. Hidden-type ear molds sacrifice efficiency by reducing intensity and introducing distortion into the signal. These factors are roughly proportioned to the length of the air column between the receiver and the ear. Day has advocated wearing the receiver in the ear where it can be seen. This prompts speakers to enunciate clearly.

The standard hearing aids are very similar in their performance characteristics. Much of the difference in cost between different makes of hearing aids is attributable to the service of dealers in assisting and encouraging new users of hearing aids. For this reason the service policies of the dealer are more important than the make of instrument, especially for the person wearing an aid for the first time.

Since the hearing aid is a signal booster only, it cannot be expected to amplify wanted sounds and suppress unwanted sounds, or to clarify poorly enunciated speech. Amplified sound is most helpful for persons with conduction losses, but is of limited benefit for persons with perception loss. Amplification is of least benefit to the ear with sharp dips or drops in the pure-tone curve, or the ear which distorts the signal as in patients with Ménière's disease.

Persons whose threshold for the better-hearing ear is 35 decibels or more will benefit from use of a hearing aid. Those whose loss is between 35 and 75 decibels usually experience satisfactory results. With losses between 75 and 95 decibels the results justify wearing the instrument.

A hearing aid is of doubtful value to the patient whose hearing threshold for the speech frequencies in the better ear is 95 decibels or more.

The most recent major development in hearing aids is substitution of the transistor for the vacuum tube. This results in a noteworthy decrease in power consumption, and thus in battery costs. Laboratory reports indicate that transistor instruments compare favorably with vacuum-tube instruments in range and fidelity of amplification for speech. However, clinical comparisons reveal a preference for the tone qualities of the vacuum-tube instruments. Instruments in which only the power tube is replaced by a transistor combine the best features of the two types.

Instruction by Parents

Instruction in the home by parents is of utmost importance to the hard-of-hearing child, particularly for the child of preschool age. It is important that training begin as soon as the defect is recognized.

The basic objectives of training in the home are fourfold: (1) talk to the child as much as possible, taking care to talk at close range and to face the child when talking, (2) associate words with objects and actions, (3) encourage the child to speak, (4) encourage contact with hearing children. Do not build up the idea that the hard-of-hearing child differs from other children.

Parents need help in order to instruct the child effectively. Advice to parents is available through the following: Institute for Parents, University of Minnesota; local hearing societies, Minneapolis, St. Paul, Duluth and Rochester; Audiology Clinics, University of Minnesota and Mayo Clinic; Committee on Conservation of Hearing, Minnesota State Medical Association; and John Tracy Institute, University of Southern California, Los Angeles, California.

School Instruction

School instruction plays a vital role in training of the hearing-handicapped child. School instruction is available in Minnesota.

Nursery schools for hearing children are valuable in developing the social contacts of the hard-of-hearing child, and should be used where special schools are not available. Special nursery schools are maintained by the Minneapolis Hearing Society and the St. Paul Hearing Society. Private boarding-school facilities are available at the Robey-Allen School in Faribault.

The public school systems of many communities maintain speech and hearing therapists to aid the hearing-handicapped child.

Minnesota Maternal Mortality Study

By the MATERNAL MORTALITY COMMITTEE
of the Committee on Maternal Health,
Minnesota State Medical Association

THIS REPORT is the fourth concerning the state-wide Minnesota Maternal Mortality Study. The material to be presented, which has not been previously reported, includes all maternal deaths occurring from April 1, 1952, through March 31, 1953, hereafter referred to as the "1952 Survey." References will be made to previous reports dealing with the study in 1941-42, 1950 and 1951.[1,2,3] Details regarding the method by which the study is carried out have been published.[2]

As in previous years, all deaths associated with pregnancy and those occurring during a period of three months postpartum are included regardless of cause of death (Table I). Deaths due to chorionepithelioma are also included. The study thus includes many deaths in which there is no obvious direct relationship between pregnancy or the postpartum state and the death, but the study has made it amply clear that death certification information cannot be relied upon in attempting to distinguish "obstetric" from so-called "non-obstetric" deaths.[4] Exclusion of any maternal deaths from detailed study would therefore necessarily be done on an arbitrary basis. It has been considered preferable to include all deaths and to report a gross or over-all mortality rate. For purposes of comparing the Minnesota Maternal Mortality rate with that of the United States generally the rate excluding deaths considered "non-obstetrical" by the committee is also shown in Table I. As indicated in Table I the mortality rate for 1952 closely approximated that for 1951. The low rate is considered further evidence of the continuing excellence of the obstetric care being administered by Minnesota physicians.

TABLE I. MATERNAL DEATHS IN MINNESOTA. STUDIES FOR 1941, 1950, 1951 AND 1952

	Number Deaths	Number Births	Gross Mortality Rate Per 1000 Live Births†	Maternal Mortality Rate Per 1000 Live Births§	U. S. Maternal Mortality Rate Per 1000 Live Births
1941	112	55,293	2.03	1.68	2.8*
1950	68	76,074	0.89	0.59	0.83**

TABLE II.
SOURCE OF REPORT OF MATERNAL DEATHS

	Number	Per Cent
Cases found from death certificates (with or without preliminary reports from physician, hospital, etc.)	135	73.8
Sources other than death certificates	48	26.2
Cross-match of death with birth certificate 24-13.1%		
Others 24-13.1%		
Total Deaths 1950, 1951, 1952	183	100.0

Source of Reporting

The source of reporting of the maternal deaths for the past three years is shown in Table II. The percentage in each category for each of the three years has been approximately the same. It can be seen that approximately one-fourth of the cases were found by other than the usual means and therefore would not be included in the ordinary reporting of the maternal mortality rate. Many of the deaths so discovered are so-called non-obstetric deaths, but many others are not. In the past year they have included such cases as an air embolus from attempted self-induced abortion, a death from arteriolosclerotic toxemia occurring three weeks postpartum and a death from postpartum hemorrhage.

Cross matching of all death certificates of women aged fifteen to forty-five years with birth certificates has led to the discovery of twenty-four cases in three years. Another twenty-four cases were found through a variety of sources including reports of hospitals and physicians. Such reports are now required by the State Department of Health within three days of the time of death of a patient dying in association with pregnancy

TABLE III. ANALYSIS OF DEATH CERTIFICATES

	No.	Per Cent	No.	Per Cent
Death certificates correct and complete in all details	57	31		
Death certificate correct in all details reported	54	30	111	61
Death certificates incorrect			72	39
Death certificates incorrect as to cause of death			52	28
Total maternal deaths (1950, 1951, 1952)			183	100

	1941		1950		1951		1952	
	No.	Per Cent	No.	Per Cent	No.	Per Cent	No.	Per Cent
Obstetric deaths	93	83.0	46	67.6	39	68.4	33	56.9
Non-obstetric deaths	19	17.0	22	32.4	18	31.6	25	43.1

or the postpartum state. It is felt that no maternal deaths in Minnesota are now being missed with the possible exception of some associated with pregnancies of less than twenty weeks duration in which the filing of birth certificates is not required and occasional cases occurring in undelivered patients. It seems likely that a correction factor of considerable magnitude is applicable to rates being reported from states where similar efforts at case findings are not carried out. In reports arrived at by ordinary means this error is added to that involved in the exclusion of "non-obstetric" deaths. Further gross errors follow the use of unchecked death certificates for information concerning maternal mortality rates (Table III).

Inaccuracies of Death Certificates

The data in Table III indicate that it is hazardous at best to arrive at conclusions based on information derived from unchecked death certificates. Only 31 per cent were complete and correct and 39 per cent were incorrect in some detail. Perhaps the most significant feature is the fact that thorough evaluation of the cases has led the committee to change the diagnosis of the cause of death in 28 per cent of the cases. The inaccuracies were of many types, and not always unintentional. A common error was to make a positive diagnosis on the death certificate when none was possible. There have been several deaths each year in which the true cause of death could not be determined even after complete autopsies were done. The cause of death in such cases should have been listed as unknown, yet in each instance a definite diagnosis was inserted on the death certificate. In 1952 the cause of death in one instance was listed as pulmonary embolism and the patient actually died of postpartum hemorrhage. In another instance a patient known to have a normal heart died as a result of drowning. The death certificate was signed by a lay coroner with the cause of death being listed as acute cardiac failure actually due to mitral heart disease. Another patient whose death certificate showed the cause of death as pulmonary embolism actually died of air embolism from air pumped into her veins under pressure through an empty transfusion bottle. Still another patient whose death certificate showed epilepsy as the cause of death actually died of postpartum hemorrhage. Many more examples from each year's survey could be cited.

Results of 1952 Survey

A most notable achievement of 1952 was the reduction of the number of deaths considered preventable to ten or 17.2 per cent of the total (Table IV). This would scarcely have been believed possible eleven short years ago when there were no less than eighty-two preventable deaths or 73.2 per cent of the total for that year. Part of the reduction in numbers of preventable deaths may be accounted for by the fact that as shown in Table V there was a further reduction in the number of deaths due to "obstetric" causes. The majority of the preventable deaths each year are in this group. On the other hand, the reduction of the absolute numbers of deaths due to obstetric causes is itself a real indication of improvement in care.

There are other evidences of improvement in care such as is indicated by a review of the operative deliveries (Table VI). While the number of operative deliveries in 1952 did not change significantly, the remarkable fact is that only three (15.8 per cent) were considered not indicated. This compares with approximately 40 per cent in the years 1950 and 1951 combined. Only four patients who died in 1952 were delivered by cesarean section. Adequate indication existed for three of these operations. One unindicated mid-forceps and one unindicated version and extraction were done. Of interest were seven post-mortem cesarean sections all said to have been done within five minutes of death. No living infants resulted. In previous years of the study five other post-mortem cesarean sections were done again with failure in all.

Serologic tests for syphilis were done in greater numbers in 1952 (Table VII). A much larger increase took place in the number of Rh determinations carried out (Table VIII). This was done early in pregnancy in twenty-nine cases or 63 per cent of the patients registered for care, and in five of the cases where it was not done early the patients were primigravidas and the indication therefore not so urgent.

The number of autopsies performed is shown in Table XIV. The percentage in each category for the past three years has been approximately the same. While 38.8 per cent adequate autopsies is considered good and is, of course, a vast improvement over the 8 per cent obtained in 1941, there is room for more improvement here. The majority of the failures to obtain autopsies are due to physician inertia. The twenty-one cases in which autopsy was not requested in 1952 include five coroners' cases.

More consultations were obtained in 1952 (Table IX), and it was thought indicated in only eight of the cases in which it was not obtained. However, further consultation was indicated in the case of four patients seen by one consultant and in many other instances consultation was obtained too late to be of value.

None	8		6		13		11	
Totals	112	100.0	68	100.0	57	99.9	58	100.0

The data in Table X shows a very gratifying increase in the frequency with which pelvic measurements were done. Notwithstanding the improvement, measurements were not done or were incompletely done in more than one-half of the patients who died. It is difficult to understand why this is true. The evaluation of the pelvis necessary to satisfy the minimum requirements as defined by the committee include measurement of the transverse diameter of the outlet (satisfied by the "fist" test), a measurement of the diagonal conjugate and palpation of the sacrum and ischial spines.

The amount of time and effort involved in this evaluation beyond that required for an ordinary pelvic examination is negligible. The rewards involved do not require repeating here. There is evidence that some re-education regarding the value of the various pelvic measurements is needed in some areas. In the past two years fifteen of eighteen incompletely measured pelves were evaluated only with respect to the external measurement including the interspinous, intercristal, intertrochanteric and Baudelocque's diameters. These measurements are now widely recognized as being valueless in estimating the capacity of the true pelvis although they have some value for other purposes. Yet in each instance the physician involved apparently felt that he was satisfying the necessary requirements regarding pelvic mensuration.

The data regarding care given in the prenatal period, during labor and delivery and in the puerperium to patients who died during the four years of the study are shown in Tables XI, XII and XIII. The minimum requirements for adequate obstetric care adopted by the committee have been published.[2] Adequate care was given in a significantly higher percentage of cases in 1952, but there is room for much improvement. In the most significant categories, faults in care which contributed to the patients' deaths, particularly gratifying reductions took place in 1952, For example, in only 9 per cent was faulty care in labor and delivery contributory to the patient's death as compared to 68 per cent in 1941.

Causes of Death

The primary causes of death are listed in Table XV. Significant of the trend in obstetrics in Minnesota is the fact that over 40 per cent of the deaths associated with pregnancy or the postpartum state were due to non-obstetric causes. The fact that poliomyelitis accounted for as many deaths as hemorrhage, the leading "obstetric" cause of death, seems particularly noteworthy. The data in the table are largely self-explanatory. The deaths due to hemorrhage in the past three years are considered in a subsequent paragraph. Of the patients who died of toxemia in 1952, two had hypertension preceding the pregnancy. One of these died undelivered of a probable cerebral vascular accident and the other died of uremia three weeks postpartum. Four others died of eclampsia. The eclampsia followed very fulminating pre-eclampsia and three of these deaths were considered non-preventable. The fourth followed severe pre-eclampsia of at least three weeks duration. Both deaths due to amniotic fluid embolism were proven at autopsy. The deaths from air embolism followed attempted self-induced abortions. The inclusion of the two deaths associated with heart disease in the "obstetric" group might be questioned because one died of congestive failure from hypertensive heart disease three months postpartum and the other died of cardiac arrest at surgery for ligation of a patent ductus arteriosis fourteen weeks postpartum. The three deaths listed in the non-obstetric complications as due to intracranial hemorrhage apparently bore no relationship to the pregnancy. None of the three had toxemia. Two deaths oc-

curred during pregnancy and one on the day of delivery.

The leading cause of death for the second consecutive year and for the third of the four years of the study was hemorrhage and shock. It is quite apparent that it is here that the greatest opportunity for improvement in the mortality rate lies. Hemorrhage is far and away the greatest cause of preventable deaths (Table XVI). It accounts for more than three times as many of these as the next leading cause.

Delivery of patients by accouchement forcé and improper use of pituitary extract during labor are two well-recognized means of inviting trouble. These two accounted for one-third of the deaths due to hemorrhage in the past three years (Table XVII). There is no indication whatever for accouchement forcé. In no instance in which its application led to the patient's death could any justification for the procedure be found. Forceful dilatation of the cervix and forceps deliveries were often carried out in acute emergencies during labor in the unthinking and obviously false belief that delivery of the patients would accomplish something to ameliorate the situation. One patient developed premature separation of the placenta and severe shock during labor. Without any preliminary shock treatment she was anesthetized with chloroform, the cervical dilatation was completed manually and mid-forceps extraction was done. The patient expired from hemorrhage and shock in less than two hours. In another instance cervical dilatation from five centimeters was completed manually followed by a difficult forceps rotation and extraction because of "epilepsy." This patient died of hemorrhage approximately eight hours later. One patient with placenta previa at thirty-one weeks gestation, another with toxemia and a third with probable premature separation of the placenta were delivered by accouchement forcé. All died of hemorrhage. In still another instance a patient was making good progress after eighteen hours of labor when for no understandable reason the physician undertook to complete the dilatation manually and deliver the infant by means of a mid-forceps extraction. This patient died of hemorrhage thirteen hours later.

The abuse of pituitary extract during labor led to five deaths. Two of these resulted from severe lacerations of the birth canal from which patients bled to death while the other three developed frank ruptures of the uterus. In general, the indications for the use of the oxytocics was either inadequate or non-existent. The recognized rules relating to the safe methods of administering pituitary extract were violated in each instance. In the only case in which the pituitrin was given in dilute solution by continuous intravenous drip, the patient was a para 8. The danger of intramuscular use of pituitary extract in any quantity is indicated by the case of a patient who developed a precipitous labor and severe vaginal and cervical lacerations following administration of only two doses of pituitrin of 1 minim each. The patient died of hemorrhage.

Another large group of deaths due to hemorrhage is made up of those resulting from postpartum uterine atony. In this group there was, in general, failure to anticipate hemorrhage in instances of prolonged exhausting labor, difficult forceps deliveries, after deep anesthesia, in the presence of twins or hydramnics and at cesarean section. Treatment was inadequate. Probably the single most effective means for correcting or preventing postpartum hemorrhage due to atony is the administration by continuous intravenous drip of a dilute pitocin solution. This was not used in a single case in this group. The situation was often aggravated by the use of general anesthesia to examine the generative tract or to insert packing. Such anesthesia was not necessary. The utero-vaginal tract was usually inadequately exposed and explored, and packing, when it was used, generally simply obscured the true situation. Packs were used in eight instances in this series of deaths due to hemorrhage and in not one did it serve to arrest the hemorrhage. There was frequently failure to appreciate the true emergency nature of the situation and to secure adequate help.

One other fact stands out when deaths due to hemorrhage are considered. Blood is now so widely available that adequate amounts were on hand in all except two instances. However, in all except three instances the blood administered was given too late and/or in inadequate amounts.

Summary and Conclusions

1. A brief general summary of the results of the Minnesota Maternal Mortality Study for the period April 1, 1952, through March 31, 1953, has been presented. Certain comparisons are made between these results and those of similar studies done in three previous years in Minnesota.

2. There were fifty-eight deaths associated with pregnancy or the postpartum period in the 1952-1953 period among 78,990 live births for an over-all maternal mortality rate of 0.73 per 1,000 live births. The rate when deaths due to non-obstetric complications are excluded was 0.42. This is almost identical with the rate for the preceding year.

3. A most remarkable reduction in the proportion of deaths that were considered preventable took place in the past year. Only 17.2 per cent were considered preventable as compared with 42.1 per cent of the deaths in the preceding year and 73.2 per cent of those that occurred in 1941-1942.

4. There was a further increase in the percentage of deaths associated with pregnancy but due to non-obstetric causes from 17 per cent in 1941-1942 to 43.1 per cent in the most recent survey.

5. Approximately the same proportion of delivered patients who died were delivered by operative means in the most recent year of the study. However, only 15.8 per cent of the operative deliveries were considered not indicated as compared with 60 per cent in the preceding year.

6. The inaccuracies of ordinarily reported maternal mortality rates and of death certificates is discussed.

7. Complete pelvic measurements were obtained in 45.7 per cent of registered patients who died. Of those incompletely measured, external measurements including the interspinous, intercristal, intertrochanteric and Baudelocque's diameter were determined in most instances while the much more significant intertuberous and diagonal conjugate diameters were ignored.

8. The primary causes of maternal deaths in Minnesota in the 1952 study are tabulated. Hemorrhage was again the leading cause of death.

9. An analysis of the cause of "obstetric" deaths in 1950, 1951 and 1952 showed that hemorrhage accounted for 28 per cent of the total and almost one-half of the obstetric deaths which were considered preventable. Hemorrhage accounted for more than three times as many preventable deaths as the next leading cause, toxemia.

10. Some of the factors involved in the deaths due to hemorrhage are discussed. The principal ones included accouchement forcé, improper use of pituitary extracts during labor, and inadequate and delayed replacement of blood.

Fractures of the Elbow

WESLEY H. BURNHAM, M.D.,
Minneapolis, Minnesota

OF THE MAJOR extremity joints, the elbow suffers the greatest from injuries to its surfaces. Since the functions of the upper extremity are largely those requiring dexterity, great demands are placed on this joint to provide a wide range of motion of its articulating parts. The articulation between the ulna and the humerus combines great stability with flexion and extension movement through a range of about 150 degrees. The articulation between the radius and the humerus combines this same range of flexion and extension movement with rotation of about 135 degrees at any point throughout the flexion and extension arc. The stability of the joint is further increased by an articulation between the head of the radius and the ulna.

Study of the anatomical relationships of these various articular surfaces reveals a precision of fit which cannot be disturbed more than a small amount if the motions of the elbow are not to be restricted. A thorough knowledge of the anatomy and functions of the elbow joint is a primary requirement for successful treatment of fractures of this joint. To this knowledge must be added the recognition of the soft tissue damage which occurs with fractures in this region. Particular care must be exercised during the recovery period to prevent this damage from leading to permanent disability. No joint in the body suffers more from overly zealous and injudicious manipulations during the recovery period.

The intelligent treatment of fractures of the elbow must be preceded by x-ray studies of good quality. The interpretation of the x-ray must be based upon exact anatomical knowledge of the bony and cartilaginous parts. The operator must have sufficiently good films and he must study those films carefully so that all displacements are visualized before treatment is begun. Certain of the fractures in this region occur primarily in youth while others are usually found in adult life. Some of the more common fractures of the elbow will be discussed according to the age group in which they are usually found.

Fractures Occurring Chiefly in Adults

Head of the Radius.—When falling on the outstretched hand, force is transmitted up the shaft of the radius and directed against the capitellum of the humerus. With an added valgus strain, the radial head may yield. In the presence of pain in the elbow with tenderness over the head of the radius and discomfort on pronation and supination movement, a fracture of the radial head must be suspected, and if routine x-ray studies do not reveal a fracture, further films made in varying degrees of pronation and supination should be made. Three degrees of fracture should be recognized:

1. A small marginal fracture with only mild displacement or a moderate sized marginal fracture with no displacement.
2. Marginal fractures with moderate to severe displacement.
3. Comminuted fractures of the head.

The first type of fracture can be treated with the use of a sling and early gentle exercise. Immobilization with a cast or a posterior plaster splint will give some comfort but should be discontinued within a week. Fractures of the second and third types usualy unite with deformity of the head and are accompanied by damage to the articular surface of the capitellum and should be treated by excision of the head. If excision is to be undertaken, it should be done within the first few days after the accident and should not be delayed until weeks or months later when it becomes obvious that the end result will be poor. Late excision of the head seldom improves the result. In the treatment of these fractures as well as all fractures of the elbow, passive stretching in any manner must be rigidly avoided since this

---

Presented at the annual meeting of the Northern Minnesota Medical Association, Willmar, Minnesota, September 10, 1954.

delays recovery and frequently leads to unnecessary permanent loss of elbow movement.

Olecranon.—Fractures of the olecranon with separation require accurate reduction and immobilization until healing is complete. This can sometimes be accomplished by closed method, but the majority of such fractures are best treated by open operation and internal fixation employing wire suture or screws. When a screw is employed, it must engage the cortex of the distal fragment in order to obtain sufficient purchase in the bone. If wire is employed, it should pass through a drill hole in the distal fragment, but through the triceps tendon and immediately proximal to the olecranon fragment and not through the easily fragmented proximal fragment. Both a simple loop and a figure of eight loop should be employed, and the wire should be pulled very tight before twisting. The fixation should be so secure that no plaster is needed after the operation. If a plaster cast is applied, the patient awakening from anesthesia may struggle against the plaster and disrupt the reduction in spite of good technique. This will not take place where only elastic bandaging is used.

Comminuted fractures of the olecranon are usually not suited to either open or closed reduction. Excision of the comminuted fragments and suture of the tricepts tendon of the distal fragment leads to good functional result. Instability of the elbow does not result unless the elbow was dislocated anteriorly at the time of the fracture or unless the fragments of the olecranon constitute more than half of the semilunar notch.

Intercondylar Fractures.—"T" and "Y" fractures of the distal end of the humerus commonly display marked rotation of the condyles and separation of the capitellum and the trochlea. If not accurately reduced, proper fitting of the articular surfaces of the radius and ulna is lost leading to considerable disability. These fractures are usually best treated by closed method employing a judicious amount of skeletal traction through the olecranon and molding of the fragments by external manipulation. Open reduction may cause more abundant new bone formation which blocks joint movement and should, therefore, be employed only when necessary and then with a minimum of dissection. The posterior approach gives the best visualization and is the most convenient.

Capitellum.—The force of a fall transmitted upward through the radius may cause the hemispherical capitellum to shear off from the humerus and become widely displaced and free in the joint. This fragment can rarely be accurately replaced by manipulative method, although a single trial is usually justified. Open reduction permits accurate replacement. The pressure of the head of the radius then maintains reduction without the necessity for internal fixation.

Fractures Occurring Chiefly in Children

The proper diagnosis of fractures in children and the assessment of their severity depends upon a knowledge of the ossification centers which are present in the cartilaginous ends of the bones. Without a knowledge of the constant and the inconstant ossification centers about the elbow, serious fractures may be overlooked or a false diagnosis of fracture may be made in a normal elbow. Since many of the fractures of the lower end of the humerous chiefly involve the cartilage at the end of the bone, the actual fracture line may not be visible and the serious nature of the injury not recognized upon casual inspection of the x-ray film. Failure to accurately reduce such fractures commonly leads to greater deformity and physical handicap in adult life than the fracture of the shaft which is permitted to unite in marked angulation. In determining the injury to the elbow of a child, films of the opposite elbow made in the same direction may be exposed and the position and shape of the ossification centers compared.

Supracondylar Fractures.—In the usual type of supracondylar fracture, the distal fragment is displaced and rotated posteriorly. In the lateral x-ray of the elbow, a line drawn through the center of the epiphysis for the capitellum forms an angle of about 40 degrees with the longitudinal axis of the shaft. In this type of fracture, the angle is reduced and the epiphysis may be found to lie in the longitudinal axis or may be displaced posterior to it. Manipulative reduction of the fracture by applying traction and then flexion usually results in a very satisfactory replacement. Immobilization in a flexed position maintains reduction, but the combination of swelling and excessive flexion may lead to ischemia and disaster if not closely attended. If the normal forward tilt of the distal end of the humerus is not accurately restored, there will be loss of either flexion or extension movement to the same extent that this reduction fails to approximate the normal Failure to reduce any angulation seen in the anteroposterior x-ray will lead to the unsightly increase or decrease in the carrying angle of the arm and frequently to tardy ulnar palsy. Residual rotation of the fragments in the axis of the arm may lead to loss of ability to place the hand behind the head or behind the back.

In the more unusual type of supracondylar fracture, the distal fragment is angulated forward. Reduction is accomplished by fully extending the arm and immobilization should be in the same position.

Transcondylar Fractures.—These fractures pass transversely through the olecranon and coronoid fossae. Accurate reduction is essential to avoid bone block and subsequent loss of movement. Closed manipulation similar to that for supracondylar fractures is the method of choice.

Lateral Condyle Fractures.—This fracture line passes largely through cartilage in children and is not seen on the x-ray film. The fragment is commonly rotated up to 90° in the frontal plane and 90° about the longitudinal axis due to the pull of the wrist and finger extensor muscles which attach to the lateral epicondyle. In the presence of this displacement, the anteroposterior x-ray film displays an epiphysis for the capitellum which has the hemispherical shape normally seen in the lateral view. The lateral x-ray film may show the "half pear" shape which is normally seen in the anteroposterior view. When displacement is severe, open reduction is almost always needed. After anatomical replacement of the fragment under direct vision, a suture of catgut is usually sufficient to maintain reduction in the plaster cast. Failure to recognize and accurately replace this fragment results in progressive distortion of the elbow into a position of cubitus valgus and subsequent tardy ulnar palsy.

Medial Epicondyle.—Avulsion of the medial epicondyle may lead to only minimal displacement or to displacements of up to one centimeter. Such disruptions do not require open reduction but heal satisfactorily with fibrous union. When the elbow is forced into severe valgus and dislocated at the time of injury, the medial epicondyle may drop into the joint where it becomes an obstacle to reduction of the dislocation. Closed reduction may be accomplished at times by increasing the valgus of the arm while tensing the flexor muscle mass by extending and supinating the wrist and fingers. When this does not succeed in withdrawing the epicondyle from the joint, open operation is clearly indicated for replacement of the epicondyle and suture with catgut.

Upper Radial Epiphysis.—The head of the radius does not commonly fragment in children, but the neck of the bone more readily compresses, resulting in a greenstick fracture. At times the fracture may lead to severe tilting of the head. The head fragment with its epiphysis must never be excised in children because the loss of the growth center leads to shortening of the bone, loss of support of the radial side of the wrist and the deformity of a club hand. By placing the elbow under a varus strain and by pressing against the displaced head with the thumb, closed reduction is frequently successful. If manipulation does not succeed and the tilt of the epiphysis is more than of moderate degree, open reduction for accurate replacement is essential. Internal fixation is not necessary since reduction is maintained by pressure of the capitellum.

Summary

Fractures of the elbow must be reduced with special care in order to prevent permanent disability. Thorough knowledge of the anatomy and functions of the elbow joint is prerequisite to intelligent treatment. Accurate knowledge of the number, location, and shape of the ossification centers is essential in proper diagnosis and treatment of elbow injuries in children. Some fractures of the elbow must be treated by early open reduction. Passive stretching adversely effects recovery, but active exercise should be encouraged after immobilization is removed.

Anal Pruritus

HOWARD M. FRYKMAN, M.D.
Minneapolis, Minnesota

THE controversial subject of anal pruritus has flooded the literature with innumerable theories and thoughts as to the etiology and treatment of this condition. Many of these suggestions have received enthusiastic support initially, and then have gradually been abandoned. Some of the established etiologic factors will be reviewed, stressing the importance of the bacterial flora of the colon and diet as contributing factors in the production of anal pruritus. Recommendations for effective therapy will also be considered.

The anal and perianal skin are unusual in that very little stimulation is necessary to produce a perceptible irritation and the sensation of itching. This portion of the body is richly endowed with sensory nerve endings and physiologically displays a maximum readiness to itch. Longo[5] has shown that the only other region of the body which has as great a tendency to itch is the meatus of the external ear. In these two hyperirritable areas only minimal stimuli are necessary to produce itching and the consequent desire to scratch. Scratching, infection and prolonged irritation soon result in lichenification which greatly increases the state of hyperexcitability. This produces the vicious scratch-itch cycle which is very difficult to interrupt. This cycle must be broken, and the patient must refrain from scratching if any results are to be expected from therapy.

The gross pathology of the pruritic area is usually characteristic in appearance. Lichenification is usually present to some degree and the more chronic the process the thicker the skin. The normal radiating anal skin folds are usually found to be raised and edematous and often excoriated from scratching. The skin changes, however, depend upon the chronicity of the disease process, the various forms of medication and treatment that have been used, and the amount of scratching the patient has done.

Anal pruritus in the vast majority of cases is a *symptom complex* and ordinarily is not produced by any one sole factor. Usually a variety of etiologic factors are combined to produce this state of persistent perianal itching. This condition is a definite pathologic entity and should not be treated lightly. Patients with pruritus should not be dismissed with some ointment or suppository nor should they all be labeled as psychoneurotics as is so frequently done. All the possible etiological factors should be carefully studied in each case to make intelligent and effective therapy possible. First, it is very important to obtain an adequate history in these patients. This should include the duration of the disease process, the time of greatest severity of symptoms, as well as the relation to defecation, baths, menstrual cycles, and ingested food and drugs. Dietary habits and the presence or absence of frequent soft stools are very important. The patient should be asked about the presence of athlete's foot or other skin disease elsewhere on the body. It is also important to determine whether allergic manifestations have been present. Next, a detailed proctologic examination should be done which should include stool examinations for parasites and an estimation of the pH of the rectal secretions. A routine laboratory examination of the urine should be done in all cases to rule out diabetes.

1. *Common Ano-rectal Pathology.* — Local pathological conditions of the anus or rectum which allow leakage of rectal secretions onto the surrounding skin are important etiological factors in anal pruritus. Common conditions such as prolapsing internal hemorrhoids, redundant rectal mucosa, anal fissures and fistulae, hypertrophied anal papillae or fibrous polyps which protrude from the anus *all* allow mucus to

---

Presented at the annual meeting of the Northern Minnesota Medical Association, Willmar, Minnesota, September 10, 1954.

escape onto the perianal skin. Frequently these secretions are very irritating. On purely a mechanical basis, however, even if the discharge was non-irritating, the constant presence of moisture between the buttocks produces a chafing and maceration of the skin. Usually the chief complaint of patients with protruding hemorrhoids and the like, will be in reference to such symptoms as bleeding and protrusion, but if questioned they usually volunteer the information that periodic episodes of itching occur.

All patients with a moist anus, however, do *not* have a true persistent anal pruritus and this is where the other etiological factors are concerned. This is also the reason why the surgical correction of all existing anal and rectal pathology in cases of pruritus ani will sometimes fail to cure the patient of the troublesome itching. External anal pathology such as skin tags and hypertrophied skin folds are also important since they make proper cleansing of the perianal skin very difficult. A factor which is very frequently overlooked in the production of a moist anus is redundancy of the rectal mucous membrane. This represents excessive looseness of the rectal mucosa in its attachment to the muscularis of the rectal ampulla. A certain amount of mobility of the mucous membrane is normally present, but through constipation, straining at stool, age and general wear and tear, the degree of slack between the layers of the rectal wall greatly increases. The excessive mobility and prolapsing of the rectal lining provokes an irritation and hyperemia of the mucous membrane in and above the internal hemorrhoidal area, which in turn effects excessive secretion of mucus. This mucus puddles above the intact sphincter and intermittently leaks through onto the perianal skin. Obvious anorectal pathology should be corrected surgically. One cannot expect a favorable response to therapy in patients with anal fistulae or pathology of an equally obvious nature which causes the skin to be constantly bathed in moist secretions.

The significance of a vaginal discharge is also frequently underestimated. Anal pruritus is often aggravated by vaginal secretions which run backward over the perineum and many of these patients will also have an associated vulvar pruritus. The leukorrhea causes the sensitive perianal skin and perineum to be kept constantly moist, and with chafing and maceration the skin becomes susceptible to secondary infection. The anal pruritus will not respond properly until the vaginal discharge has been eliminated.

2. *Chemical Irritants.*—Chemical irritation is probably the most important of the etiological factors involved in the majority of cases of anal pruritus and until recently its importance has been almost completely overlooked. Tucker and Hellwig[15] many years ago reported that the gross and microscopic changes in the skin in anal pruritus were characteristic of a chemical dermatitis. More recently some very important work has been done on the hypothesis of chemical irritation in pruritus which has given us a much more logical basis for the treatment of this condition. Slocumb,[9] in an exhaustive study of a series of cases of anal pruritus, found that the great majority of these patients had an increased pH of the rectal secretions, and he believed that the pruritus was due to seepage of this alkaline mucus onto the perianal skin. He also found that the increased alkalinity of the rectal contents was directly correlated with the flora of the colon. Through dietary measures he was able to alter the pH of the secretions of the rectum by altering the relative percentages of the Gram-positive and Gram-negative bacteria in the colon.

The second important study was done recently by Friedman, Haskell and Snape[2] who did microchemical studies on secretions obtained from the anal canal of patients with anal pruritus. They separated their cases into the "moist pruritus," or those in which the affected area was reddened, eroded, macerated and moist, and the "dry pruritus," characterized by marked hypertrophy and thickening of the skin folds. They were able to identify trypsin or trypsin-like enzymes in the rectal secretions of approximately 80 per cent of the "moist pruritus." In another group of patients with non-pruritic anorectal disease 20 per cent were found to have significant amounts of proteolytic enzymes in the rectal secretions. A similar figure (approximately 20 per cent) was obtained in the control group with no gastrointestinal pathology. These investigators believed that the proteolytic enzymes in the secretions leaking out onto the perianal skin was primarily responsible for the skin irritation. This group, however, did not indicate whether an elevated pH or increased alkalinity was found.

With these two studies one can come to some very definite conclusions as to the primary etiology in many cases of anal pruritus, and it is possible to treat the condition in a more intelligent and specific manner. Normally the pH of secretions obtained from the rectum vary from pH 6.5 to 7.5. In the majority of patients with anal pruritus the pH reading will be from 7.5 to 9.0. The prolonged seepage of alkaline secretions onto the perianal skin would in itself be an irritant, but the presence of the proteolytic enzymes is probably more important. Trypsin is most active in an alkaline medium with the maximum enzymatic effect being reached at pH 8.0 (Fig. 1) and this effect is maintained as the alkalinity increases. It will be noted that this is also the pH range of the rectal secretions in the majority of patients with anal pruritus. Trypsin is also mildly active in a neutral or mild acid medium but the activity rapidly and progressively decreases from a maximum at pH 8.0 to complete inactivity at pH 5.5.

Nitrazine paper is used for the purpose of determining pH readings. This is a rather rough method of estimating pH values, but it is accurate enough to definitely determine whether or not increased alkalinity is present.

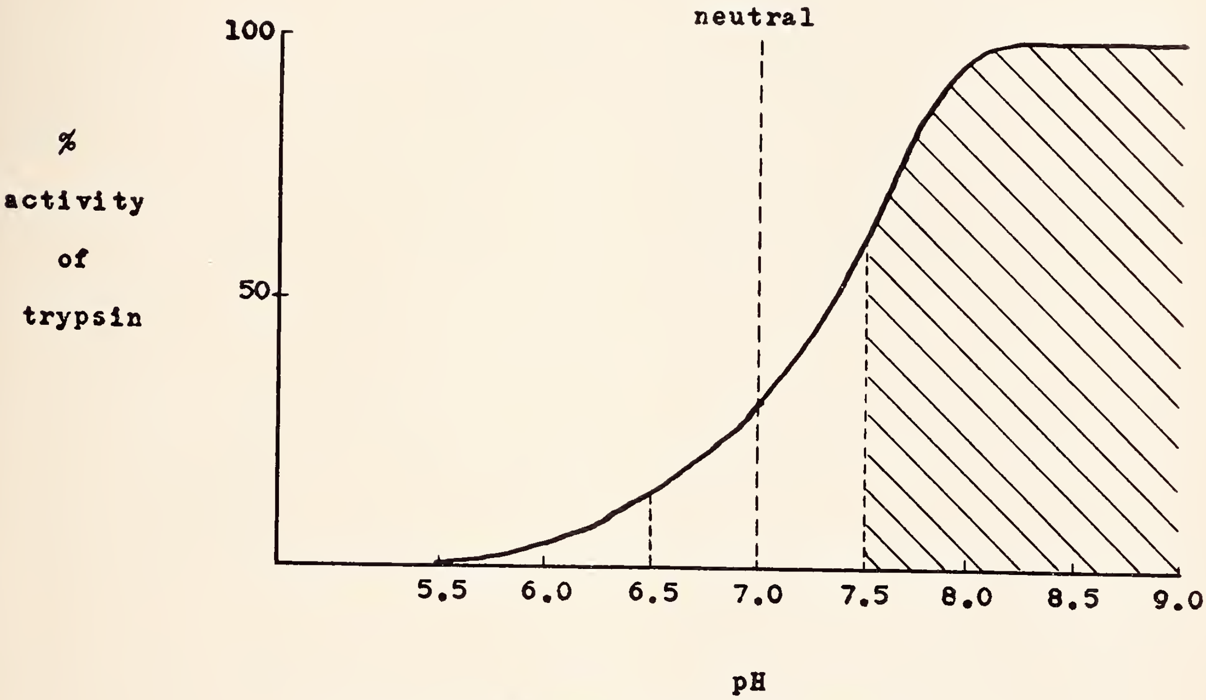

Fig. 1. From *The Journal of General Physiology.*[6]

The irritation of the skin in anal pruritus can be compared in a sense with the irritation of the skin of the abdominal wall following ileostomy or colostomy. High concentrations of proteolytic enzymes are present in the small bowel where they are active in protein digestion. Gradually neutralization of these enzymes occurs in the colon so that usually only minimal amounts can be detected when the fecal material reaches the rectum. In some individuals, for various reasons, inadequate neutralization of these enzymes occurs. We have all experienced a soreness and irritation of the anus following a bout of diarrhea. The increased peristalsis produces liquid stools which allows insufficient time for the neutralization of the proteolytic enzymes. When the diarrheal stool comes in contact with the external skin, the enzymes produce the irritation by a process of digestion. A comparison can also be made with the care necessary to protect the skin about an ileostomy stoma, transverse and sigmoid colostomies. Great care is required to prevent digestion of the skin from ileostomy secretions. Less care is necessary to prevent irritation about a transverse colostomy and with a sigmoid colostomy the skin usually requires little care. Progressive inactivation of the proteolytic enzymes as the fecal mass passes through the colon renders the stools less irritating. The irritation produced about artificial abdominal stomas, however, produces a burning sensation rather than persistent itching. A possible explanation for this may be Longo's study[5] mentioned previously, which showed the marked tendency of the perianal skin to itch. Many patients with anal pruritus will volunteer the information that the itching is severe following a bowel movement. The increased irritation following defecation is usually due to improper cleansing of the anus. Small amounts of stool containing minute quantities of proteolytic enzyme lodge between the radial perianal skin folds and irritate the skin until either the stool is removed or the action of the enzyme is spent. This is the reason why proper anal hygiene is so important in patients with pruritus ani.

Another recent factor in anal pruritus has been the generalized use of oral antibiotics. Aureomycin and terramycin seem to be the greatest offenders but persistent perianal itching is also seen following the use of others. The rectal secretions obtained from pruritic patients who have received these agents are uniformly quite alkaline in reaction (pH 8.0—9.0) and it may be assumed that proteolytic enzymes are also present. The high pH is due to a reduction in the number of the Gram-negative colon bacteria which normally form lactic acid in the intestinal tract by fermentation of carbohydrates.

Rettger[9] has likened the large intestine to "a veritable culture tube in which definite bacterial types appear to be constantly struggling to gain supremacy." As the colonic flora gradually returns following sterilization of the bowel by antibiotics, an overgrowth of Gram-positive bacteria may occur, which suppresses the growth of the normally predominant Gram-negative organisms. The alkaline contents of the small bowel is then no longer neutralized by the Gram-negative acid-producing colon bacteria, and the fecal mass passes through the large bowel maintaining a high alkaline pH. The inactivation of the proteolytic enzymes is likewise impeded. According to Zinsser's Bacteriology,[16] the Gram-negative colon bacteria normally constitute about 75 per cent of the intestinal flora, with the Gram-positive rods and cocci forming the remainder of the colonic organisms. Kendall,[4] Rettger,[9] and others have proven that definite changes may be brought about in the relative percentages of colon bacteria by purposefully adjusting the diet. Slocumb's[10] study routinely showed a predominance of Gram-positive instead of Gram-negative bacteria in his patients with elevated mucosal pH and anal pruritus. Through dietary measures he was able to reverse this ratio, and when the Gram-negative bacilli again becomes most numerous, the pH of the rectal secretions also was found to have been reduced to the normal range. With additional supportive measures the anal pruritus disappeared. Recurrences were reported and stool cultures again showed a predominance of Gram-positive instead of Gram-negative bacteria. Individual dietary habits over prolonged periods of time with a resultant change in the flora of the colon may well be one of the fundamental factors in the etiology of anal pruritus. Dietary habits are also the probable explanation for the fact that anal pruritus following oral anti-biotic therapy or otherwise, is rarely seen in children except for those with oxyuriasis infestation.

3. *Fungus Infections.* — Fungus infections play a definite role in anal pruritus, but they are important mainly as secondary invaders. Terrell and Shaw[15] reported an incidence as high as 60 per cent in cultures taken from the perianal area. Fungi can occasionally be cultured from normal skin but they usually do not grow and produce symptoms unless certain definite conditions are present for their growth. The perianal skin and the interdigital spaces between the toes offer ideal places for active growth of these organisms because of the moisture, heat and improper ventilation of the areas. Another factor which makes the perianal skin particularly vulnerable to fungus infections is the presence of the apocrine sweat glands, or scent glands. These glands produce a secretion having a higher pH, as well as a higher percentage of carbohydrate and protein than is found in ordinary perspiration.

Harry[3] and other investigators have stressed the important role played by pH in the defense mechanism of the skin. All the cells of the normal epidermis have an acid reaction (average pH 5.4) which serves as a protection to the skin. As Prinz and Ereaux[8] stated, "many pathogenic bacteria and fungi are very sensitive to acids, but grow abundantly in a slightly alkaline environment." In rubbing or scratching the perianal skin, if the epidermis is penetrated even to a small degree, weeping occurs and the adjacent skin immediately assumes the alkaline pH of blood plasma (pH 7.4). This again offers ideal conditions for the growth of pathogenic bacteria and fungi. The two most common types of fungi involved are the Monilia and Epidermophyton organisms. Occasionally cases of anal pruritus can be cleared by using fungicidal therapy alone but this is the exception rather than the rule. Usually additional therapeutic measures are necessary to give the patient lasting relief. Some clinical improvement can be expected, however, if the secondary fungus infection can be eradicated or reduced in severity.

4. *Allergy.*—Allergy is difficult to rule out as a causative factor in anal pruritus. If the patients do not respond to other measures, they are then studied from an allergic standpoint. Elimination diets and skin tests may be employed to attempt to identify the allergan and a therapeutic trial with antihistaminic drugs may be tried. With the introduction of the antihistaminics, allergy was strongly implicated as an etiologic factor and numerous enthusiastic reports were published with very high curative rates. For a period of time these drugs were administered routinely to all patients with pruritus ani, but the results which others had reported could not be duplicated. The use of antihistaminic drugs is now restricted to those cases in which a definite allergic element is present or seems to be present or in those cases where other means fail. Allergy has been definitely established as an etiologic factor in pruritus ani but the number of cases is small.

5. *Intestinal Parasites.*—These are not major factors in anal pruritus in adults, but pinworm infestation should be considered especially in the night scratchers. Abel[1] has stated that pinworms are the usual cause of anal pruritus in children. Tests to determine the presence of pinworm eggs on the perianal skin should be a routine procedure in adults as well as children, since positive findings are common enough to justify the consideration of their presence. If the pinworm ova are found, the patient should be given adequate treatment with oral gentian violet. The uncomplicated cases will clear up immediately. In adults, however, if oxyuriasis is found in a full blown case of anal pruritus, the presence of the parasites is probably only contributory and additional methods of treatment will be necessary.

6. *Mechanical Factors.*—The anal region is constantly being exposed to trauma of one type or another. The passage of hard stools, the use of rough toilet tissue, improperly fitting underclothing which traumatize the area on walking, etc., are all factors. The wearing of a perineal pad during the menses will often irritate the perianal skin and usually is very aggravating to an existing anal pruritus. This group can be readily identified and is but one of the several factors usually involved in producing this condition.

7. *Psychogenic Factors.*—Stokes[11] and others maintain that there are always tension factors in the background of chronic anal pruritus, "the itching being the focal manifestation of a neurotically predisposed skin." They maintain that the patient sets up a vicious cycle of projection of his anxieties upon the perineum. Some authors associated with large clinic groups have considered 90 per cent of the cases of anal pruritus to be a neurodermatitis. In the last edition of Ormsby,[7] "Diseases of the Skin," anal pruritus is discussed under the neuroses. This is a grave injustice to the majority of patients suffering from this condition. Although it is true that patients with chronic pruritus ani are frequently very nervous, it is often found that as soon as the itching has been alleviated, the degree of nervousness is greatly reduced. While in most cases, nervousness and tension may be contributory in anal pruritus, they do not form the underlying basis for the persistent anal itching. Nervous tension and chronic anxiety may serve to amplify and perpetuate otherwise brief periods of itching by keeping the patient unusually alert or attentive to sensations from the perianal region. Trauma from scratching and the unusual awareness of the condition may start the vicious scratch-itch cycle. Once this cycle has been established therapy is usually ineffective unless the patient can stop scratching the area.

8. *Constitutional Disease.*—Diabetes is probably the most common constitutional disease with secondary anal pruritus, although other constitutional diseases with skin manifestations may involve the perianal area. Patients with eczema

and psoriasis should probably also be included in this category. If the diseased perianal skin is only a part of a dermatitis involving other portions of the body, it is fruitless to attempt to treat only the pruritus ani *per se*.

Treatment

1. *General Considerations.* — Patients with anal pruritus should be reassured and told the nature of their trouble at the first consultation. The type of treatment to be used should be carefully explained so that the patient realizes the value of the instructions that are given him. The futility of scratching the area must be stressed, since any additional rubbing or scratching only serves to aggravate the scratch-itch cycle and makes the condition worse. Underwear and trousers should be worn loosely to avoid any additional stimulation. Woolen underwear is especially bad as a mechanical irritant in these people. Women should be instructed to discard girdles and corsets which bind the buttocks tightly together. These foundation garments aggravate the condition by allowing improper ventilation between the buttocks and produce chafing and irritation.

2. *Anal Hygiene.*—The patient must definitely alter the manner used to cleanse the anus after bowel movements. No harsh toilet tissues are allowed since nothing will start the scratch-itch cycle as readily as vigorous rubbing of the anus. The patient is instructed to use a wad of toilet tissue or cotton soaked in water to cleanse the area. The anus should be thoroughly washed with the wet pledgets to remove all traces of fecal matter and then dried by blotting with dry tissues.

No soap should be used about the anus, since it is a definite irritant if not completely removed. The alkaline soap also removes the protective oily film and creates an alkaline medium favorable to the growth of secondary invaders. Many patients are instructed to apply vaseline to the skin about the anus before bathing to protect the area from soapy water.

3. *Diet.*—Adherence to a strict diet is most important, at least during the early phase of treatment. A modified acid-ash diet should be followed since in leaving an acid residue it will reduce the excessive alkalinity of the large bowel. This diet should include those foods which produce lactic acid on fermentation in the intestinal tract. Especially important are dairy products such as cultured buttermilk, yoghurt, cottage cheese and other cheeses. Cultured buttermilk should be consumed in as large quantities as possible. It is sometimes desirable to add beta-lactose to the buttermilk because of its ready fermentation to lactic acid. Bread, cereals of all kinds and spaghetti are other carbohydrates which may be used. Of the fruits, only prunes, plums and cranberries are considered to have an acid residue because of the formation of benzoic acid. Although meat and eggs are considered to be acid-ash foods, Kendall[4] has shown that the excessive consumption of proteins will promote the growth of the putrefactive flora of the bowel and tends to inhibit the growth of the desirable Gram-negative colon organisms. For this reason a moderate reduction in the consumption of protein is required.

The addition of viable Lactobacillus acidophilus organisms to the diet, in one form or another, is also very beneficial. This is done routinely in the postantibiotic cases of pruritus and proctitis. Many forms of these cultures are available, but recently Lactinex tablets have been used with success. These compressed tablets, composed of a combination of viable L. acidophilus and L. bulgaricus organisms, are consumed with whole milk. Rettger[9] as shown that the simultaneous administration of lactose and L. acidophilus bacteria will replace the putrefactive flora of the colon with an aciduric flora. Lactobacillus acidophilus organisms will also establish residence in the colon. It is not possible to secure implantation of Lactobacillus bulgaricus in the bowel, which is the organism most commonly used in the production of cultured buttermilk. Although the action of L. bulgaricus is transient, with prolonged use it also enhances the growth of the desirable Gram-negative bacteria by also forming lactic acid on fermentation of carbohydrates.

Foods which produce an alkaline residue should be restricted. These include fruits and leafy vegetables in general, with the exception of the fruits mentioned above. Citrus fruits are very common offenders. They greatly increase the alkalinity of the stool and even the moderate use of orange juice and grapefruit juice may aggravate an anal pruritus. Peppers and heavily spiced foods should be omitted because of the irritant effect on the digestive tract. Alcohol is another offender, and beer should be completely restricted if there is a tendency toward the production of soft stools. This dietary regime is starchy and not too tasty but the patients seem to tolerate it quite well.

4. *Rectal Irrigations.*—Slocumb[10] advocated the use of a mild lactic acid solution for rectal irrigations. He found lactic acid to be more effective than dilute hydrocholoric or boric acid in maintaining a pH of about 6.5 in the rectal ampulla. The purpose of this irrigation is twofold. First, it reduces the alkalinity of the rectal ampulla by neutralizing the alkaline secretions and, secondly, it cleanses the rectum of any stool and mucus which may be present. It will be recalled that Friedman et al[2] found proteolytic enzymes in the rectal secretions of a large percentage of patients with anal pruritus. The washing away of these enzyme containing secretions is probably the greatest function of the irrigations. Slocumb[4] recommended that this irrigation be used once daily.

A modification of this technique has been found to be more effective in some cases. One pint of a .15 to .20 per cent lactic acid solution is used as a rectal douche. This solution can be easily prepared by adding one teaspoonful of a 20 per cent lactic acid solution to a pint of tap water. The frequency of the irrigations or low enemas depends upon the acuteness of the individual case. In patients with a moist, red and eroded perianal skin it has been found advantageous to use the irrigation three or four times daily until the acute symptoms have begun to subside. Local applications and supportive treatment must, of course, be used along with the cleansing acid enemas. The average chronic case of anal pruritus is instructed to irrigate himself twice daily at the onset of therapy. After a period of time when the itching subsides and the skin has begun to approach the normal, the irrigations may be reduced to once daily, once every second day, and then discontinued if the patient will adhere to the acid-ash diet. If dietary indiscretions cause a recurrence of the itching, the patients are told to resume the irrigations until the symptoms again subside. These lactic acid irrigations are not a "cure-all" for anal pruritus, but it has been found to be one of the most effective methods of therapy at our disposal, giving more benefit to a greater number of patients than any other single method of treatment..

5. *Local Applications.*—In the very acute types of pruritus with the typical red, weeping skin nothing is more beneficial or gratifying than the use of cold moist packs. Usually a 1:10 Burow's solution or 1:4000 potassium permanganate is used. The potassium permanganate has the advantage of also being effective against the secondary fungus infection which may be present. In the acute type of case the application of ointments usually only serves to aggravate the condition. A mechanism which will quickly bring relief from severe itching is the application of an ordinary ice collar to the perineum, holding it in place with a belt or T-binder. This may be used in conjunction with the cold moist packs. The maintenance of subnormal temperatures anesthetizes the nerve endings and very soon stops the itching. This is a very useful procedure which should be explained to the patients.

The majority of the cases of anal pruritus which are seen have been grossly overtreated. In an effort to stop the itching the patient has usually tried numerous home remedies and proprietary medicines. The majority of medications sold across the counter in drug stores contain symptomatic antipruritics in excessively high concentrations. The effectiveness of these preparations in controlling the itching soon wears off and a secondary irritation is produced which eventually makes the condition worse. In general it may be stated that the mildest medications which will give the patient relief will ultimately give the best results.

New preparations are constantly being introduced for the treatment of anal pruritus; however, some of the old time-worn remedies which have generally been discarded have not lost their excellent qualities. Unna's Soft Zinc Paste (pasta zinci mollis U.S.P.) has been found to be one of the most effective preparations available, forming an excellent water-repellent protective application. Because of the mildness of this paste it may be used indefinitely to protect the perianal skin.

Fungicidal therapy is indicated if the pruritic skin appears to be complicated by a fungus infection. As stated previously, most mycotic infections in anal pruritus are secondary and additional therapeutic measures are necessary, but improvement can be expected if the fungus infection can be eradicated or reduced in severity. Mild preparations of gentian violet, malachite green, Castellani's paint, and other dyes have been used, and all are quite satisfactory for local application. The fatty-acid fungicidal preparations (Desenex, Sopranol, etc.) have also been used. The commercially available preparations of these fungicides, however, are far too strong for use on the sensitive perianal skin. They should be diluted to one-half or one-third their initial strength with an appropriate ointment base. Tar preparations are often quite valuable in the treatment of chronic cases with lichenification of the skin. They are usually used in strengths of 2 to 5 per cent. The tar ointments are generally effective in reducing the chronic inflammation and thickness of the skin. Ointments containing local anesthetics are unnecessary in the treatment of anal pruritus. The itching can be stopped with other means and the eczematoid dermatitis often produced by sensitivity reactions to the anesthetic agents can be avoided.

Recently hydrocortisone preparations have been widely used in the treatment of many dermatoses including anal pruritus. In many cases it promptly reduces the inflammation and edema in the involved skin and stops the itching. Local hydrocortisone therapy, however, is no panacea or one-shot treatment for all cases of chronic anal pruritus. Several cases have been seen in which the application of hydrocortisone has made the condition worse. Sulzberger[13] has reported similar experiences. It is fruitless to expect hydrocortisone ointment, or any other ointment, to be effective in the acute, red, weeping types of anal pruritus. Conventional methods must first be used to relieve the acute inflammatory reaction before local hydrocortisone therapy is attempted. The 2.5 per cent hydrocortisone ointment is much more effective in the treatment of anal pruritus than is the 1.0 per cent preparations. A very small amount of the 2.5 per cent ointment should be applied to the involved area two or three times daily and thoroughly massaged into the skin. In cases where a favorable response occurs, improvement is usually evident within two to three days after treatment is begun. In some cases the itching will stop within a few hours. If no improvement is noted within seven days, the hydrocortisone therapy should be discontinued since no further beneficial effect can be expected. After the pruritus has subsided, the 1.0 per cent ointment is usually adequate to keep the itching under control, but its daily use is often necessary to prevent recurrences. In the presence of scattered excoriations in chronic cases the addition of Neomycin to the hydrocortisone seems to be helpful in eradicating the secondary infection and promoting more rapid healing of the eroded areas.

Sulzberger[13] has stated that the therapeutic action of locally applied hydrocortisone is based on a local hormonal action of the steroid itself on the skin. The local effectiveness is also obtained without undesirable systemic effects and no contraindications were found to its continued use on small body areas in a large series of cases.

Hydrocortisone is a valuable adjunct to the treatment of anal pruritus but its use should be combined with dietary changes and other therapeutic measures at our disposal to produce lasting cures. Treating the symptoms rather than the disease as a whole cannot be expected to produce satisfactory long-lasting results.

6. *X-ray Therapy.*—Local x-ray therapy has been used extensively in the treatment of pruritus ani. It is most effective in the chronic cases with lichenification, and it acts by decreasing the hyperexcitability of the pruritic skin and helps to break the scratch-itch cycle. Many patients will respond favorably to this type of therapy and then become refractory to it. If the x-ray treatments are continued too long a radiodermatitis will ultimately develop. For this reason the indiscriminate use of x-ray should be eliminated. Before resorting to x-ray every effort should be made to control the condition with other means. There are too many patients suffering from both the pruritus and a radiodermatitis. When this unfortunate combination is found, the usual type of therapy is ineffective and radical procedures such as a subcutaneous perianal neurotomy must be used to give the patient relief.

7. *Surgical Methods.*—The injection of long-lasting local anesthetics beneath the perianal skin is used occasionally to break the scratch-itch cycle when the patient has insufficient will power to keep from scratching. This will stop the itching for a sufficient period of time so that adequate general and local therapy can be effec-

tively started. Usually an aqueous preparation of Diothane and Benzyl alcohol is used. Fewer complications in the form of slough and abscesses can be expected with this preparation than with the long lasting local anesthetics in oil.

If redundancy of the mucous membrane exists, it may be corrected as an office procedure with the injection of sclerosing solutions, or surgically at the time of removal of other coexisting anorectal pathology. Sclerosing solutions injected into the submucosa promote fibrosis and fixation of the mucosa to the muscularis. Usually five per cent phenol in olive oil is used for this purpose although other sclerosing solutions are also effective. If the injections are carefully given and intramucosal injections are avoided, sloughs and other complications are quite rare.

Radical operative procedures for anal pruritus, such as Ball's subcutaneous perianal neurotomy, have been abandoned. However, when surgical procedures are done on pruritic patients for the removal of obvious anorectal pathology, the perianal skin is routinely undercut at the same time. Severing the perianal sensory nerve fibers at this time is a relatively simple procedure, and it does not prolong the healing period. If the undercutting is thoroughly done, the patient will be completely relieved of any itching until sufficient time has elapsed for the nerve fibers to grow back. This usually requires several months during which time adequate measures can be taken to treat the skin and otherwise restore normal physiology to the area.

HEARING LOSS IN CHILDREN

(Continued from Page 8)

Day schools for the hard of hearing are maintained in Minneapolis, St. Paul and Duluth.

Speech clinics are available at the University of Minnesota, the University of Minnesota at Duluth, St. Cloud State Teachers College, and Moorhead State Teachers College.

The Minnesota School for the Deaf at Faribault is a state-maintained boarding school for hearing-handicapped children. Its enrollment is limited.

Carcinoma of the Common Duct

Report of Two Cases

WILLIAM O. FINKELNBURG, M.D.
Winona, Minnesota

ACCORDING to Renshaw, Durand Fardell first described carcinoma of the common duct in 1840. Since that time numerous authors have reported small series of cases. Kirshbaum and Kozell[2] reported thirty-two cases in 13,330 consecutive autopsies at the Cook County Hospital. Niebling[4] found sixty cases in 14,000 operations on the biliary tract and 12,000 autopsies at the Mayo Clinic. McGlinn[3] found five in 9,000 routine post-mortem examinations and Glen and Davis[1] report three from the New York Hospital from 1932 to 1951. From these series it is readily seen that the disease is relatively infrequent even in the larger medical centers. For this reason it seemed to me that two cases occurring within three months' time in a small community hospital would be of interest to the practicing physician. Of further interest is the fact that only 345 operations on the biliary tract were performed during the years 1949 through August 1954. No other cases were found during this period.

The sex distribution of carcinoma of the common duct is found to be more equal than in carcinoma of the gall bladder with most authors reporting a slight preponderance on the male side. Also, in contrast to gall bladder carcinoma, biliary calculi are found to be present less frequently, but they do occur in about fifty per cent of the cases. This is still a rather high incidence and for this reason many authors suggest a possible etiological relationship between biliary calculi and carcinoma of the bile ducts. Other workers, notably Boyd, Barlow, and Dick[4] have pointed out the similarity of normal bile constituents to known carcinogenic agents.

The clinical manifestations of carcinoma of the common duct are indistinguishable from any other obstructive type of jaundice. The most common manifestation is a progressive jaundice usually without pain although pain does occur with surprising frequency. The jaundice is accompanied by acholic stools, anorexia, weight loss, and pruritus. In one of our two cases the patient had no complaints other than jaundice and pruritus. In various series a palpable gall bladder was present in only thirty per cent or less of the cases. The carcinomas are predominately adenocarcinomas with the infiltrating type most prevalent in the common duct. Microscopically three general types are noted: (1) scirrhous, (2) mucous, and (3) a papillary type. Metastasis occurs early both regionally and at a distance and recurrence following surgery is common.

The early diagnosis of these tumors is difficult and seldom made. In fact, the exact preoperative diagnosis is usually obscure and it remains for laparotomy to disclose the type of obstruction. Consequently many of these tumors are discovered unexpectedly or in a late phase when regional and distant spread has occurred beyond any possible hope of surgical cure.

Palliative surgery to relieve the jaundice and its complications and pain has not been encouraging.

Local extirpation of the lesion followed by reconstruction of the bile ducts has been tried with varying success. It is distressing to report that both of these cases died, one surviving her surgery for a period of two months. It is to be hoped that with the further development of radical surgical techniques and of the biochemical anti-carcinogenic armamentarium more long-term survivals will be effected.

With these brief remarks on the disease itself, I should like to present two cases of carcinoma of the common duct occurring at the Winona General Hospital within a three-month period. Both cases presented the classical picture of jaundice and in neither case was the diagnosis made preoperatively.

Case 1.—A seventy-two-year-old white woman was first seen November 23, 1953, complaining of jaundice.

Awarded Southern Minnesota Medical Association Medal for best case report submitted at the annual meeting, Winona, Minnesota, September 13, 1954.

She gave a history of weight loss, anorexia, and tiredness, of one month's duration. Her husband had noticed the yellow discoloration of her skin. She gave no history of nausea, vomiting, or pain. Her general health was always good and she gave no history of having had any type of infection within the past year.

Physical examination revealed a well-developed, well-preserved white woman who was markedly jaundiced. Examination was essentially negative except for the abdomen. There was spasm of the entire right rectus muscle with the sensation of fullness in the right upper quadrant of the abdomen. No definite mass could be outlined. Pelvic and rectal examinations were essentially negative.

Laboratory examination at the time of the admission to the hospital revealed the hemoglobin to be 12.5 grams, red blood count 3,800,000, white blood count 7,200 with 76 per cent polymorphonuclears and 24 per cent lymphocytes. The plasma proteins were 6.05 grams, thymol turbidity 3.9 units, and the prothrombin time 17.2 seconds with a control at 12.2 seconds. The cephalin flocculation test was negative in twenty-four hours and one plus in forty-eight hours. The total serum bilirubin was 12.6 mgm. per cent and the urine urobilinogen was negative in a one to ten dilution. The stool was negative for occult blood.

X-ray examination of the chest revealed no evidence of intrathoracic pathology. Examination of the upper gastro-intestinal tract by means of a barium meal showed a small ulcer in the first portion of the duodenum and distortion of the duodenum by an extrinsic mass. A diagnosis of obstructive jaundice most probably malignant in origin was made and the patient was prepared for surgery.

The patient was operated upon on December 7, 1953. At laparotomy, the gall bladder was found to be markedly distended. The upper portion was thin-walled whereas the lower half was thick-walled and firmly attached to a mass located at the junction of the cystic and hepatic ducts. The hepatic ducts proximal to the mass were markedly dilated. The intrapancreatic portion of the common duct was of normal caliber. Biopsy of the liver near the gall bladder revealed adenocarcinoma. Biopsy of the mass surrounding the common duct also revealed adenocarcinoma. The gall bladder, cystic duct and the mass involving the first portion of the common duct were excised *in toto* and the continuity of the common duct was re-established by primary anastomosis over a T tube.

The patient's postoperative course was quite stormy but she gradually showed a decrease in the amount of jaundice and a slight increase in her appetite. She was discharged with the T tube in place. Her course at home was gradually down hill although she was able to be up and around part of the day and to eat three meals a day. She died on February 19, 1954, following an episode of coffee ground emesis. Her jaundice had cleared at the time of her death. A post-mortem examination was not obtained.

The pathologist's report of the tissue removed at surgery revealed adenocarcinoma of the common duct with regional infiltration into the liver and gall bladder.

Case 2.—This patient was operated upon by Dr. Roger Hartwich of Winona who very kindly provided the clinical data for this paper. The patient was a sixty-two-year-old white man who was first seen on January 2, 1954 complaining of jaundice and anorexia. He had been well until December 29, 1953, when he had complained of nausea. He had had no vomiting, no abdominal pain, no chills or fever. About one week later he noticed dark urine, light colored stools, and weakness. His past history was essentially negative and there was no history of any *injection* in the past year. He continued to work as a shipping clerk feeling fairly well on a high protein low fat diet. Because of the persistent jaundice and pruritus he was admitted to the hospital on January 28, 1954, for exploration.

Physical examination on admission revealed a well-developed, well-nourished white man who was obviously jaundiced and complained only of severe generalized itching. Entire physical examination resulted in negative findings save for the marked jaundice and evidence of pruritus.

Laboratory examination revealed a hemoglobin to be 78 per cent, the white blood count 6,000 with a normal differential. The prothrombin time was eighteen seconds with a control at fourteen seconds, alkaline phosphatase was 10 Bodansky units, cephalin flocculation one plus in seventy-two hours, and the total serum bilirubin 11 mgm. per cent. A twenty-four-hour stool specimen showed no fecal urobilinogen and the urine was positive for bile. The total protein was 7.4 grams with a normal A/G ratio.

This patient was operated upon February 4, 1954, at which time a mass involving the common duct and cystic duct was found. The tumor mass extended from the junction of the cystic and common hepatic ducts along the entire length of the common duct to the Ampulla of Vater where it stopped. The duct system proximal to the mass was markedly dilated. A biopsy of the tumor was taken which on frozen section proved to be adenocarcinoma. The duct was incised and drainage was established by means of a T tube.

The patient did well following his operation but expired suddenly on his fourth postoperative day. Postmortem examination revealed a large pulmonary embolus. Examination of the common duct and pancreas at the time of post-mortem examination revealed the common duct completely surrounded by tumor from the Ampulla of Vater approximately to its junction with the cystic duct. The pathologist's final diagnosis was adenocarcinoma of the common duct.

minimal

side

effects

ACHR

LEDERLE LABORATORIES DIVISION AMERICAN *Cyanamid* co.

One of the notable qualities of ACHROMYCIN, the Lederle brand of Tetracycline, is its advantage of minimal side effects. Furthermore, this true broad-spectrum antibiotic is well-tolerated by all age groups.

In each of its various dosage forms, ACHROMYCIN provides more rapid diffusion for prompt control of infection. In solution, it is more soluble and more stable than certain other antibiotics.

ACHROMYCIN has proved effective against a wide variety of infections caused by gram-positive and gram-negative bacteria, rickettsia, and certain virus-like and protozoan organisms.

ACHROMYCIN ranks with the truly great therapeutic agents.

Retroperitoneal Cavernous Hemangioma Associated with Hemangiomas of the Skin in a Newborn

Case Report and Brief Review of Literature

J. RICHARDS AURELIUS, M.D.
DONALD H. PETERSON, M.D.
ISMAIL NIKNEJAD, M.D.
Saint Paul, Minnesota

HEMANGIOMAS ARE the most common benign tumors of the newborn. They occur most frequently on the skin of the face and the lower extremities. The lesions are often multiple. Rambar[16] reported the occurrence of hemangiomas of the skin in 11.6 per cent of a large group of premature infants. The incidence is believed to be smaller in full term newborns. According to Fitzwilliams[6] about 16 per cent of individuals with hemangiomas of the skin have multiple lesions. Sometimes, hemangiomas can occur in two different tissues of the same individual. The simultaneous presence of hemangiomas of the liver and spleen or skin and brain has been repeatedly recorded in literature. It is these combined lesions that have given rise to many eponyms and non-descriptive diseases such as Osler-Rendu, Sturge-Webber, and Lindau's etc. Numerous reports of these combinations of hemangiomas have been recorded.

A rare site for these congenital lesions is the kidney. Up to 1951, only seventy-three cases of hemangiomas of the kidney had been reported (McCrea[11]). Still rarer in occurrence is the presence of hemangiomas in the perirenal retroperitoneal spaces. Only three such cases have appeared in the medical literature up to the present time. The extreme rarity of a retroperitoneal hemangioma is such that no mention of it appears in the standard texts and reference books on pathology. Caffey[1] fails to mention it in the differential diagnosis of abdominal tumors of children. Similarly, Willis[25] and Ewing,[5] in their comprehensive treatises on the neoplastic diseases of man take no notice of the possible occurrence of hemangiomas in the retroperitoneal spaces. For this reason, the following case is recorded, and a brief review of the literature on this subject is attempted.

Case Report

Baby D, white male, was born at 3:58 P.M. on October 3, 1953. Delivery of the head and shoulders was accomplished without difficulty, but there was some delay in releasing the hips.

Physical Examination at birth revealed the following positive findings:

1. The abdomen was distended by a large oval mass which could be palpated in the right lower quadrant and flank. The mass appeared to extend down into the right pelvis.
2. Bilateral hydroceles of both testes.
3. Two dark strawberry colored tumors, each measuring four centimeters in diameter, were seen, one on the upper lateral aspect of the right thigh, and the other on the skin over the right patella. A firm subcutaneous mass measuring two centimeters in diameter was also found in the right lateral surface of the thigh.

Family History.—Non-contributory.

Laboratory Data.—Examination of the blood revealed a positive Coomb's test, a hemoglobin of 10 Gm. with an erythrocyte count of two million. Many normoblasts in ratio of 8 per cent of the erythrocytes were present. Transfusion via the umbilical cord was carried out. Four hundred and eighty-five cc. of blood was withdrawn, and 556 cc. of whole blood was injected along with 5 cc. of calcium gluconate. The excess of blood was given because of the low initial erythrocyte count. This procedure was well tolerated.

Fig. 1. *(upper left):* Scout film of the abdomen. Note the large soft tissue mass in the right lower quadrant pushing the gas filled loops of intestine to the left.

Fig. 2. *(upper right):* Spot roentgenogram obtained during examination of the colon by means of barium enema. Forward and medial displacement of ascending colon is demonstrated. Note also the dye-filled pelves and calyces of both kidneys.

Fig. 3. *(lower left):* Photograph of the microscopic section of the tumor. Note the cavernous blood spaces. Similar picture was seen in the section of the nevi of the skin on postmortum examination.

Fig. 4. *(lower right):* Arrows point to minute calcific densities in the nevus over the right patella.

From the Department of Radiology, Ancker Hospital, Saint Paul, Minnesota.

Dr. Aurelius is Chief of the Department of Radiology, Dr. Peterson is Associate Radiologist, and Dr. Niknejad is University of Minnesota Fellow in Radiology, at Ancker Hospital, Saint Paul, Minnesota.

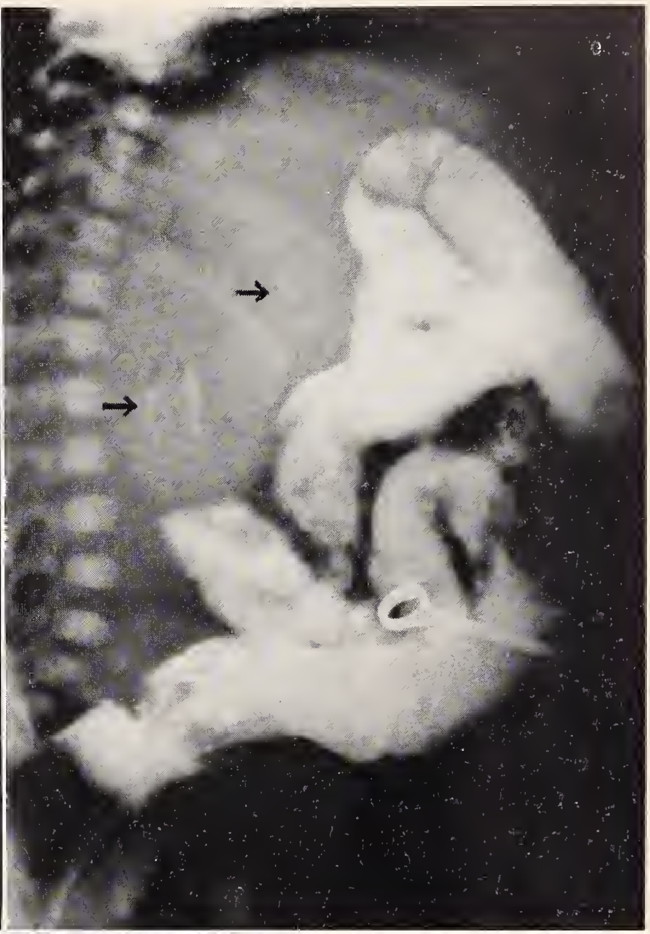
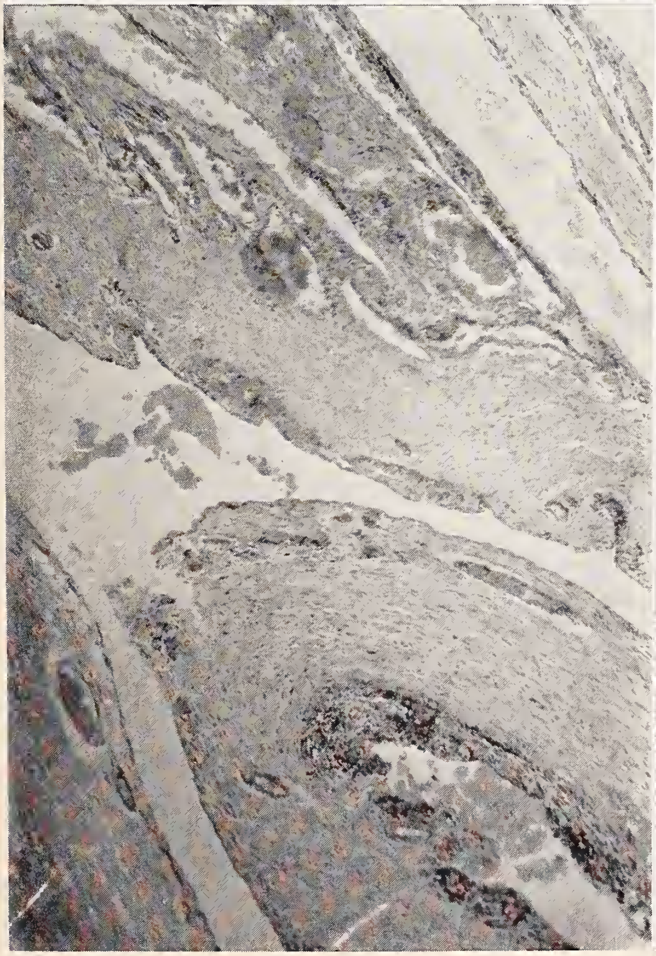
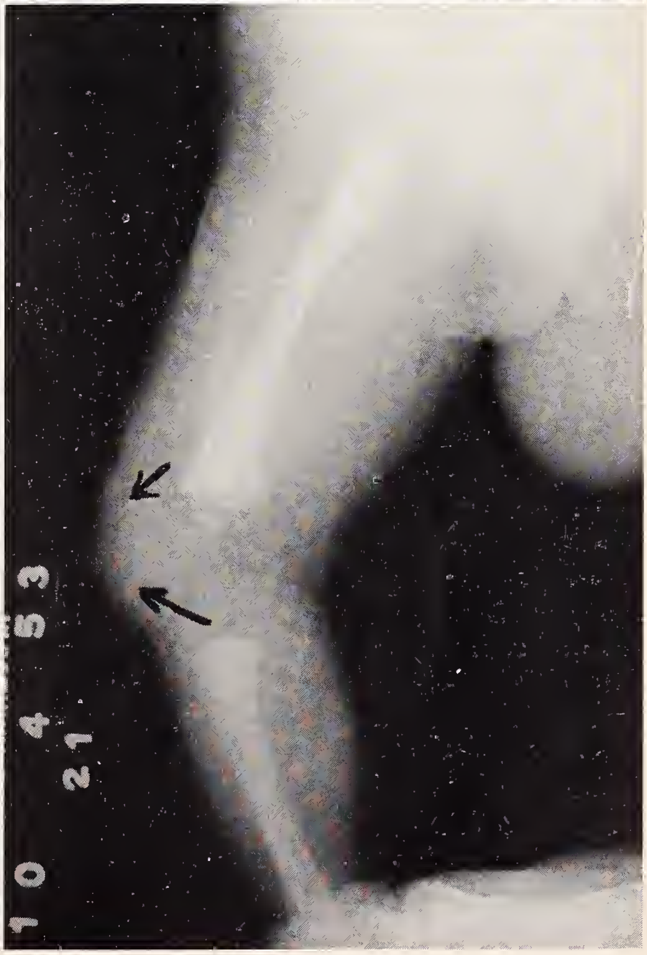
21







10 4 53
21

Roentgenological Examination.—The initial scout film of the abdomen (Fig. 1) revealed a soft tissue mass in the right lower quadrant. The mass appeared to displace the normal gas containing loops of large and small intestines to the left. There was no radiological evidence of intestinal obstruction. A roentgenogram of the right leg showed soft tissue masses which were noted on physical examination. In addition, definite calcification was noted in the tumor over the right patella. Examination of the skull disclosed a normal calvarium with no evidence of metastasis.

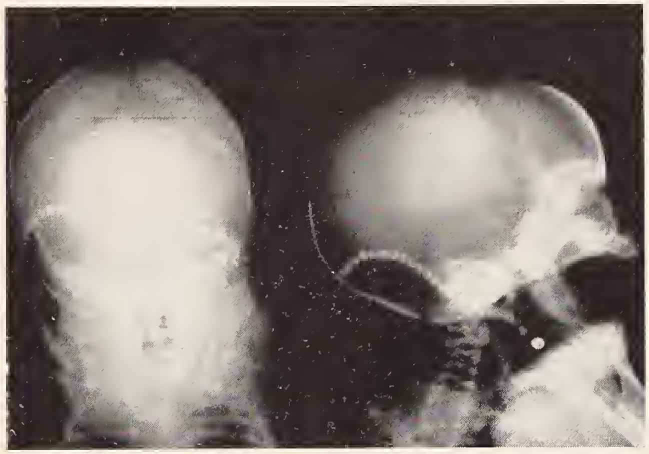


Fig. 5. Antero posterior and lateral roentgenograms of the skull show no evidence of metastasis.

In view of the presence of multiple hemangiomas of the right leg, it was postulated that the mass in the right lower quadrant could also represent a lesion of similar nature. Study of the genito-urinary tract, and examination of the colon for better evaluation of the abdominal mass were suggested. These were carried out on the following day. About 5 cc. of the urographic contrast medium was injected into the subcutaneous tissues of both buttocks. Roentgenograms obtained subsequently showed a normal urogram on the left. No contrast medium could be elicited in the right kidney. At this time, on the insistence of the surgical staff who were anxious to do an exploratory laporatomy as soon as possible, further follow-up urographic studies had to be abandoned. However, films taken during the examination of the colon, which was performed subsequently, fortuitously revealed normal urograms bilaterally (Fig. 2). It was then assumed that the retroperitoneal mass in the right lower quadrant was probably separate from the right kidney, or at least did not involve its collecting system. Thus, the previous impression with regard to the nature of the lesion was confirmed. Incidentally, the barium enema showed medial displacement of the ascending colon.

Findings at Laporatomy.—A mass of tissue measuring 9 x 7 x 2 cm. was found in the right retroperitoneal space which surrounded the anterior aspect of the right kidney, but did not invade it. A line of cleavage could easily be made between the tumor and the right kidney. The inferior portion of the mass extended to the right pelvis.

Surgical Pathology Report.—The specimen consisted of a mass of tissue measuring 9 by 7 centimeters in its broadest dimensions and 2 cm. in thickness. On section, the tissue was composed of tortuous dilated venous spaces filled with clotted blood. The largest of these spaces measured 3 cm. in diameter.

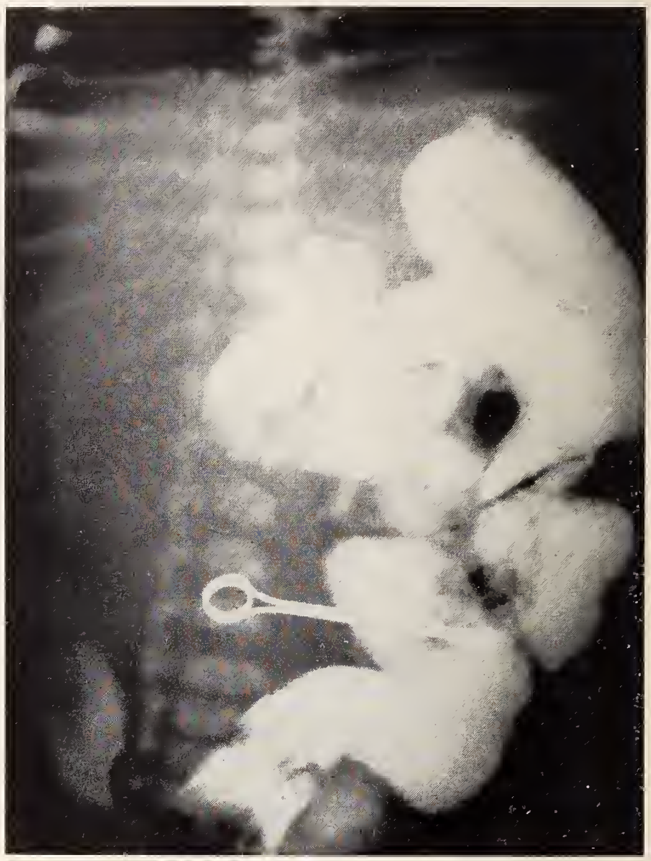

Fig. 6. Barium enema shows marked displacement of the cecum and ascending colon to the left produced by the soft tissue mass in the right retroperitoneal space.

Microscopic Description.—Sections of the tumor showed it to be composed of cavernous blood spaces many of which contained red blood cells (Fig. 3). There was no evidence of malignancy.

Pathological Diagnosis.—Cavernous hemangioma of the abdomen.

Postoperative Course.—The infant tolerated surgery well, and was returned to the recovery ward in fair condition. However, about three hours later, his respiration ceased. Artificial breathing and cardiac stimulants failed to revive the infant.

Post-mortem Examination disclosed atelectasis of both lungs. Microscopic study of the lesions of the skin revealed cavernous hemangiomas. No other finding of note was observed.

Discussion

Watson and McCarthy[24] studied a series of 1,056 cases of angiomas of the skin. Some of these cases had multiple lesions. Of this latter

TABLE I. CLINICAL SUMMARY OF THE PRESENT CASE AND THE THREE PREVIOUSLY REPORTED CASES OF RETROPERITONEAL CAVERNOUS HEMANGIOMA

Age	Sex	Symptoms	X-Ray Findings	Diagnosis Made	Associated Lesions and Fate of Patient	Case Reported By
59 yrs.	White Male	Dull aching pain in the left flank	"Slight displacement of the left ureter toward mid-line, distortion of the pelvis and calyces due to changed axis of the kidney and apparent distortion of the kidney substance in the lower pole . . ."	After Operation	Cardiac enlargement and murmur Patient died suddenly on 10th postoperative day (no autopsy)	Harris[8] 1929
32 yrs.	White Male	Generalized abdominal pains of six months duration	"Barium sulfate enema showed the cecum and ascending colon displaced obliquely as far as, and even somewhat beyond the mid-line."	After Operation	No associated lesions. Patient survived surgery and apparently cured	Millman[13] 1944
5 mos.	White Male	Rectal Bleeding	Barium enema negative	After Operation	Two hemangiomas, one overlying the right buttock and the other over the mid-sacral crest. Patient died during surgery.	Ward and Stewart[23] 1950
Newborn	White Male	Right abdominal mass discovered on physical examination (no symptoms)	Scout film of the abdomen and barium enema showed a large soft tissue mass in the right lower quadrant displacing the cecum and loops of small intestine medially.	Diagnosis suggested prior to operation	Three hemangiomas of the right thigh over the approximate distribution of cutaneous branches of L4. Died about three hours after operation.	Aurelius et al.

group, two had associated hemangiomas of the viscera. One had a hemangioma of the right kidney, and the other had a hemangioma of the sigmoid colon. Dean and McCarthy[4] state that "hemangiomas of the unusual location or extent are often part of a larger congenital pathologic complex." The validity of this statement is attested by the present case and the case reported by Ward and Stewart.[23] In both of these patients, the retroperitoneal cavernous hemangiomas were part of a diffuse similar process involving an extremity. Furthermore, Dean and McCarthy[4] call attention to the possibility of a vascular tumor of the viscera in patients with multiple hemangiomas of the skin who have bleeding of an undetermined origin.

The first retroperitoneal cavernous hemangioma was reported by Harris[9] in 1929. Since then, only two additional cases have appeared in the medical literature.[13,23] Stout[18] mentions a case reported by Hilse[10] in 1929. This, however, was actually a retroperitoneal lipoma which had areas of cavernous hemangiomas within it. This tumor recurred following surgical removal. The case of bilateral cystic lymphangiomas of both kidneys which was reported by Dasco[3] cannot be classified as hemangiomas. Retroperitoneal cavernous hemangiomas of the connective tissues of the pelvic floor have also been recorded by Frank[7] and Tapfer and Just.[19]

For the sake of brevity, the clinical history, and roentgenological findings of the four reported cases of retroperitoneal cavernous hemangiomas have been outlined in Table I.

An analysis of this table discloses an apparent predominence of these lesions in the male. However, in view of the small number of reported cases, no definite conclusion is warranted. To our knowledge, no sex affinity has been observed in the large reported series of the hemangiomas of various locations. Greater incidence of hemangiomas of the skin of the premature white infants as compared with negroes has been noted by Rambar.[16]

Due to the rarity of the visceral hemangiomas, the diagnosis is seldom made prior to surgical exploration or post-mortem examination. In the three previously reported cases, the diagnosis was made only after surgery. In the fourth case, which is the subject of the present report, the possibility of a retroperitoneal cavernous hemangioma was suggested because of the presence of several large colored lesions of the skin on the same side of the body on which the abdominal tumor was palpated and demonstrated by the roentgenogram.

Pathogenesis.—The great majority of hemangiomas are congenital in origin and are present at birth. Willis[25] believes that "angiomas are not true tumors." He considers them to be congenital malformation originating from embryonic mesenchymal cells which have the ability to proliferate and form blood vessels and also a variety of other tissues as well. Ewing,[5] on the other hand, maintains that hemangiomas are due to developmental anomalies of certain blood vessels which retain their embryonic characters. Virchow[22] attributed the formation of hemangiomas to the action of irritants on imperfectly formed blood vessels. Thoma[21] believed that these lesions are the result of mechanical disturbance such as increased blood pressure. A greater incidence of hemangiomas of the skin in premature infants in whom the temperature regulating mechanism of the body is defective led Rambar[16] to suggest that there may be a relationship between the development of angioma and the peripheral vascular needs of the infants. Finally Ribbert[17] is of the opinion that hemangiomas have their origin in embryologic rudiments.

Differential Diagnosis.—The possibilities of a Wilm's tumor and sympathicoblastoma, two of the most common malignant abdominal tumors of infancy, were considered. Absence of metastasis to the lungs, and lack of derangement of architecture of the right kidney as would be expected from a tumor of this size were against the diagnosis of Wilm's tumor. Sympathicoblastoma was thought unlikely due to lack of any discernible metastasis in the long bones and in the skull. Since the bulk of the tumor appeared to be located below the inferior pole of the right kidney, the possibility of a supra-renal hemangioma, as recorded by several authors[12,14,20] was held improbable. Other possibilities that could not be excluded by conventional roentgenographic methods were teratoma, and retroperitoneal hematoma secondary to rupture of a cortical hemangioma of the right kidney. Several instances of the latter occurrence are found in the medical literature.[2,14]

Likewise, the presence of a retroperitoneal chyle cyst as reported by Gerster[8] could not be ruled out by the available diagnostic tools.

Distribution. — Thought-provoking conjecture can be made about the interesting distribution of the hemangiomas in our patient. Yakovlev and Guthrie[26] in a scholarly analysis of ectodermoses in epilepsy draw attention to peculiar predilection of the angiomatous growths for the tissues of ectodermal origin. They believe that obvious analogies exist between the angiomatosis of the brain and the two other types of congenital ectodermoses, namely, that of Recklinghausen's and Bourneville's diseases. A case of hemangioma of the spinal cord associated with four port-wine nevi of the skin of the corresponding neuromere reported by Cobb is cited[26] as "the classical example" of the neuromeric distribution of these lesions. As early as 1911, Fitzwilliams[6] recognized this distribution and stated: "their extension and growth is intimately connected with the nerve supply of the part." In our case, the location of the retroperitoneal hemangioma opposite to the body of the 4th lumbar vertebra corresponds quite well with the distribution of the nevi which were located in the areas of the right thigh supplied by the cutaneous branches of the 4th lumbar nerve as illustrated in Figure 7.

Thus the presence of hemangiomas of the skin and a study of their distribution may help in the differential diagnosis of a visceral tumor whose nature is not known with certainty.

Summary

A case of retroperitoneal cavernous hemangioma associated with similar lesions of the skin has been presented. The literature on the subject has been reviewed. The association of hemangiomas of the skin with similar lesions in the viscera has been stressed, and their neuromeric distribution has been discussed.

Facts about Nursing in Minnesota

THELMA DODDS, R.N.

Saint Paul, Minnesota

IN CONSIDERING our common problem—meeting the nursing personnel shortage—perhaps a few facts and figures will give us a broader understanding of the problem and aid us in finding a new solution. This question of the shortage of nursing service, particularly in hospitals, is not alone the responsibility of nurses, but of doctors, hospital administrators, and other health workers as well.

The solution of our problem most frequently advanced is: "more schools of nursing will produce more nurses." Let us look at the figures (Table I).

TABLE I. PROFESSIONAL NURSING SCHOOLS

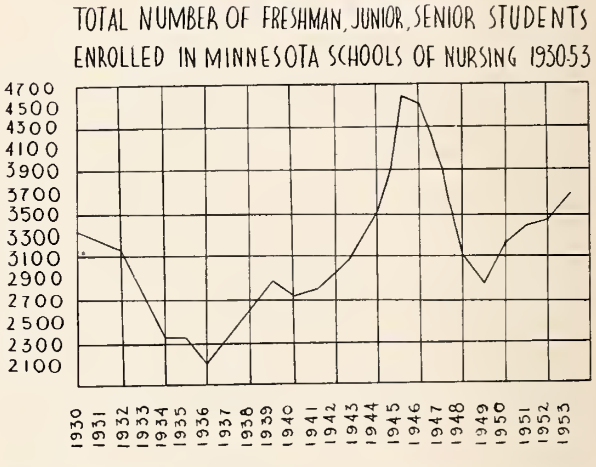
(Minnesota State Board of Examiners of Nurses)

	Number Accredited	Student Enrollment	
January, 1954	23	3,701	
" 1949	27	2,891	
" 1945	26	4,601	(peak)
" 1944	26	3,539	
" 1939	27	2,866	
" 1934	45†	2,359	

†11 Schools were in process of closing.

In 1934, there were forty-five accredited schools of professional nursing with 2,359 students enrolled. As the number of schools has decreased, the number of students enrolled has increased. In 1954, there were twenty-three accredited schools with 3,701 students enrolled. During the years 1943-1948, the United States Public Health Service through the U. S. Cadet Nurse Corps program financially supported Nursing Education and that is the reason for the increased enrollment shown for the year 1944-1945.

The total number of freshman, junior, and senior students enrolled in Minnesota schools of nursing shows a steady increase since 1936 to 1953. Again, it is necessary to keep in mind that the increased enrollment from 1943 to 1948 is the result of the Cadet Nurse Corps program. The increased enrollment from 1951 to 1953 reflects the number of students receiving assistance under the State Scholarship Aid program. More will be said about that later.



(From Minnesota State Board of Examiners of Nurses.)

Today there are twenty-six accredited basic professional nursing programs in Minnesota in twenty-three schools of nursing. Of these, twenty are three-year diploma programs, and six are four-year programs leading usually to a Bachelor of Science in Nursing degree. (Three of the six collegiate nursing schools have both Bachelor degree and diploma programs.) Eighty per cent of the students are enrolled in the diploma programs and 20 per cent in the degree programs. One school, the University of Minnesota, offers programs to graduate nurses leading to both a Bachelor's degree and a Master's degree. In addition to the twenty-three schools, thirty-two hospitals and health agencies in Minnesota provide one or more approved courses in nursing by affiliation.

Nationally the picture is the same.

You will note that since 1930 the number of schools has decreased from nearly 2,000 to a little over 1,000 in 1953, while the number of students enrolled has increased from around 80,000

Presented at the annual meeting of the Southern Minnesota Medical Association, Winona, Minnesota, September 13, 1954.

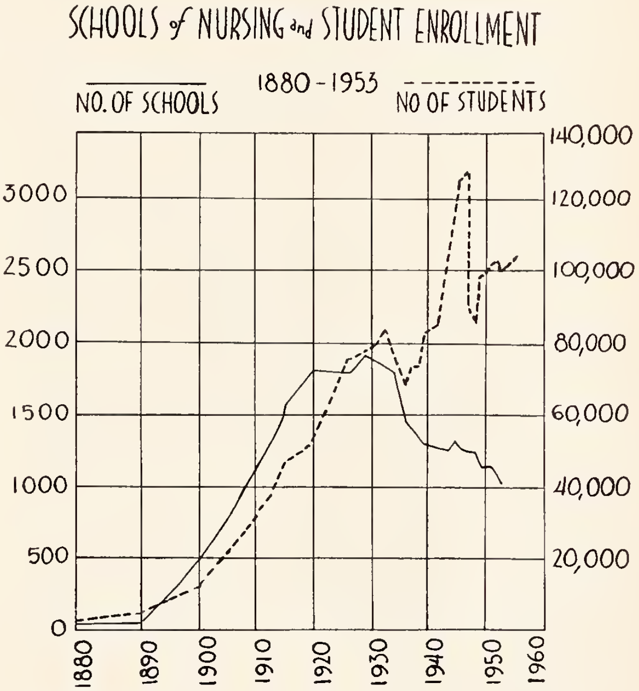
in 1930 to over 100,000 in 1953. (The peak between the years 1943 and 1948 was the result of the U. S. Cadet Nurse Corps program.)

A recent study by the American Nurses Association† shows that as of January 1, 1953, Minnesota had the seventh highest total student nurse enrollment among the forty-eight states. (Yet 1950 census figures show that Minnesota ranked eighteenth among the states in population.) The same source showed that Minnesota admitted the eighth highest number of student nurses, and graduated the seventh highest number.

In the fiscal year 1953-54, Minnesota licensed 1,466 professional nurses—980 by examination and 486 by interstate endorsement. Minnesota endorsed to other states 820 registered nurses. As of July 1, 1954, 36,603 R.N. licenses had been issued in Minnesota since the licensing law was passed in 1907. A total of 12,680 registered nurses had renewed licenses for 1954. (Many of these, however, reside outside of Minnesota or are inactive.) The A.N.A. source quoted previously† indicated that Minnesota had the sixth highest number of new registered nurses licensed by examination. Yet in 1952, Minnesota had only the twelfth highest average hospital census.

Practical nursing in Minnesota is a much newer venture, the Licensed Practical Nurses licensing law having passed in 1947. As of September 1, 1954, there were thirteen accredited practical nursing programs in Minnesota with a total enrollment of 300 students. Size of the student groups vary from eight to fifty-two; eight schools have less than twenty students enrolled. Minnesota ranks fifth highest among the states as to the number of practical nursing programs. In the fiscal year 1953-54, Minnesota licensed 300 practical nurses by examination and eleven by interstate endorsement. As of July 1, 1954, 2,958 licenses had been issued to practical nurses since 1947. A total of 2,541 had renewed their licenses for 1954. (Some of these, however, are inactive or reside outside Minnesota.) The A.N.A. study previously quoted,† indicated that Minnesota had the sixth highest number of new licensed practical nurses licensed by examination in 1952.

Many of the Minnesota Schools of Nursing, both professional and practical, could accept more students than apply for admission. Thus we can assume that no qualified applicant is denied admission to a Minnesota school of nursing because all classes are filled. Furthermore, there are at present, listed with the Minnesota Nurse Counseling and Placement Service, about twenty-five vacancies on Minnesota School of Nursing faculties. Also, many of the faculty positions are at present filled by nurses not fully qualified by education or experience for these important teaching positions. Opening more schools of nursing would not, therefore, increase student enrollment and would obviously deplete the present school faculties to a danger point. Studies that have been completed regarding the cost of a school of nursing to the hospital have indicated in most instances that the schools are not self-supporting. One study completed in Minneapolis at the Swedish Hospital School of Nursing for the year 1951, concluded that the cost to the hospital for each student in the professional school was $639.36 over and above the tuition that the student pays and the services that she contributes in her learning experience. Thus the operation of a school of nursing is an added cost to most hospitals.



(From "Facts about Nursing, 1953," American Nurses Association.)

Why are we faced with this alarming shortage of nurses? The shortage is the product of trends in medical care which we neither can nor wish to reverse. The shortage might better be expressed as an increased demand for nursing services. This increased demand has been influenced by many factors such as pre-paid hospital insurance plans, new and better medical techniques requiring more nursing service, and increased hospital construction, to mention only a few. For example, during the past five years, over 5,000 beds have been added to Minnesota hospitals.

---

†"Facts about Nursing—1953," American Nurses Association.

What have we been doing about the problem?

The Minnesota Nurses Association through its state and district committees has carried out an active student nurse recruitment program. In the year 1953-54, a total of 119 high schools of the 484 in Minnesota were visited and nursing information was distributed on career days; high school counselors were visited; five films on nursing were shown in forty schools; 5,000 brochures were distributed; MNA co-sponsored the special vocational issue of the *Minnesota Daily* providing information about the various health fields. This special edition was distributed to every high school senior in Minnesota. And these recruitment activities were financed entirely by the nurses of Minnesota!

Despite the increasing competition for women in other professional fields and in industry: (a) more nurses are practicing their profession than ever before; (b) a larger proportion of girls are entering nursing than ever before—except during the U. S. Cadet Nurse Corps period 1943-48; and (c) the average working life of a nurse is longer than ever before, largely because many more married nurses are working.*

The state Scholarship Aid program has provided assistance to 795 student nurses since the law was passed in 1951. All but two counties in Minnesota have students in schools of nursing who are recipients of the state scholarships. The criteria for awarding these scholarships is based on the financial need of the student and her ability to complete her nursing course. The maximum amount of a scholarship for the professional nursing candidate is $600, and for the practical nursing candidate is $300. In return for this scholarship, the student must practice nursing in Minnesota for one year. We plan to introduce the scholarship bill in the 1955 legislative session and would like to have the continued support of the bill by the Minnesota State Medical Association. In addition to the state scholarships, hospitals, medical groups, or communities in general might well establish local nursing scholarships, the recipients of which would be required to return to work in that community for a specified time.

If it costs a hospital $636 per student to operate a school of nursing, why isn't it just as economical for the student to be subsidized to that amount providing she returns to that community or hospital for employment as a graduate? Such an *annual* scholarship would help build up a supply of nursing personnel for the local hospital.

If "more schools of nursing" is not the answer to our problem, what is the solution? Obviously we cannot continue to maintain the status quo and wait for the return of the "good old days." We must learn to utilize the personnel we have more effectively. To do this we must cast off the shackles of tradition and scrutinize each task within the hospital to see whether it is really necessary for the welfare of the patient and whether it is being performed in the most economical manner from the standpoint of time and choice of personnel. This takes planning, not only in the nursing department but with the medical profession and hospital administrators as well. We must learn to use the knowledge and skills of each individual—professional nurse, practical nurse, attendant, nurse aide, and orderly—to its maximum.

We must see that professional nurses are assigned only those functions which require the type and amount of training they have had; that practical nurses are used in situations where some formal training is necessary but not to the same degree as the registered nurse; that attendants, nurse-aides and orderlies have an on-the-job training adequate to prepare them for their jobs. Numerous hospitals already are making progress in this regard. The key to the solution, however, lies within the individual hospital, since no two institutions present identical problems.

Sudden, Apparently Unexplained Deaths during Infancy

ROBERT B. TUDOR, M.D.
Bismarck, North Dakota

SUDDEN, APPARENTLY unexplained deaths during infancy are always tragic events with painful consequences for everyone concerned. If they are not handled properly the parents may develop an acute sense of guilt over their possible negligence in the situation.

An infant in apparently good health is put to bed in a crib or buggy or in bed with its parents. Several hours later the infant is found dead. Sometimes he is lying on his face. Sometimes bed clothes are over his head. Often in the excitement the exact conditions are unnoted. The physician who is confronted with such a death is likely to assume that the baby has smothered or that he has died because of an enlarged thymus.

Upon examining 167 autopsies of children under one year of age who died suddenly, Werne and Garrow[2] (1947), were not able to find one case in which they could prove mechanical suffocation by bed clothes. It is probable that mechanical suffocation may occur as a terminal event during a debilitating disease in a child, but there is no risk of accidental suffocation from the bed clothes in a healthy child. There is also no relationship between the size of the thymus and adrenal glands and sudden death. Rabson[1] (1949) showed the relationship between sex and unexpected natural death in New York City. In the age group from birth to four years, males outnumbered females 2.7 per cent to 2.0 per cent, while in the age group from five to nine years the sexes were equally represented. During the first five years, four times as many boys as girls died suddenly. No girls were counted among the few cases of sudden unexpected death in the second period. This is another confirmation of the often remarked lethality of boy babies. Werne and Garrow,[3] in a study of 299 cases, have shown that pathologically there are microscopic inflammatory lesions of the upper and lower respiratory tracts and vascular changes in the respiratory tract, spleen, lymph nodes and thymus in these cases. The mononuclear pneumonia which is usually found is thought to be agonal, as it also is seen following a violent death in a child. The vascular changes are usually thrombi, focal inflammation, edema and hemorrhage. According to Werne and Garrow, the chief pathological findings in sudden apparently unexplained death during infancy are acute inflammation of the upper or lower respiratory tracts; gross exudate in the middle ears and mastoid antra; acute suppurative tonsillitis; congestion of the meninges; excess subarachnoid fluid; minute focal subarachnoid hemorrhages; congestion of the mucosa of the larynx, trachea, and bronchi; foci of necrosis in the larynx and trachea; hyperemia and hemorrhage in the tracheobronchial and cervical lymph nodes; pulmonary congestion and edema; emphysema; pulmonary capillary congestion and bronchitis or bronchiolitis; focal accumulation of macrophages and lymphocytes within the alveoli and pharyngeal filling with regurgitated vomitus. The vomitus is thought to be an agonal phenomenon.

In most cases, the etiology of a sudden death in an infant is fulminating respiratory disease. Other causes of apparently unexplained death during infancy are: meningococcemia; cerebral hemorrhage; adrenal hemorrhage; obstruction from a laryngeal papilloma; coronary artery disease; anaphylaxis; anesthesia; and postoperative sepsis.

Table I is a summary of seven case reports of children who died suddenly. Pathologically, they all showed bronchopneumonia.

In summary, the etiology of sudden apparently unexplained death during infancy is usually fulminating respiratory disease. This occurs

---

From the Department of Pediatrics, Quain and Ramstad Clinic, Bismarck, N. D.

Presented at the Regional Meeting of the American College of Physicans at Bismarck, North Dakota, September 11, 1954.

TABLE I.

Case	Sex	History	Age at Death	Postmortem
1. Ryckman No. 109523 E	Male	B. wt. 7 lbs. 11 oz. Normal fullterm. Spontaneous delivery.	2 days	Bronchopneumonia
2. Tibesar No. 79975 G	Male	B. wt. 4 lbs. 3 oz. Bronchopneumonia, 3 mos.	4 mos.	Bronchopneumonia
3. Kielty No. 115656 A	Male	Erythroblastosis. Basilar meningitis. Cortical atrophy. Bronchopneumonia, 1 yr.	14 mos.	Bronchopneumonia. Internal hydrocephalus.
4. Hatzenbuhler No. 122472 B	Female	Myasthenia gravis (?)	8 mos.	Bronchopneumonia
5. Hellman No. 123893 A	Male	Common bile duct atresia. Frequent bronchitis.	5 mos.	Bronchopneumonia. Biliary cirrhosis. Biliary atresia.
6. Brady No. 130898	Male	B. wt. 6 lbs. 9 oz. Normal fullterm. Spontaneous delivery.	5 weeks	Bronchopneumonia
7. Miller No. 109338 E	Female	Congenital hemolytic anemia, 2 days. Splenectomy, 4 mos.	2 8/12 yrs.	Bronchopneumonia

more commonly in males. Agonal phenomena seen are: the presence of bed clothes over the face and around the neck; pharyngeal vomitus and a mononuclear pneumonia. In order to make a correct diagnosis a careful postmortem examination must be made in every case.

"NO PRACTICAL VALUE"

Gamma globulin as a preventive of paralytic poliomyelitis has been found "of no practical value," says Gaylord W. Anderson, M.D., director of the School of Public Health, University of Minnesota.

The supposed prophylactic effects of GG were studied during 1953 under very carefully controlled conditions by a committee appointed by the U. S. Public Health Service. More than 235,000 children were involved in these studies. The report of the committee showed that beneficial effects were not demonstrated either in the mass inoculation of children in epidemic areas or in the inoculation of family and other close contacts of patients already ill with polio.

These findings, as well as a review of the current status of gamma globulin supplies on hand and of requirements for globulin, led to the recent decision by the Office of Defense Mobilization to discontinue the rationing of GG, a program carried on by that agency since 1953. This co-ordinated distribution of globulin (for poliomyelitis) through state health departments will not be continued after December 31, 1954. According to the ODM, an increase in supply of globulin has taken place during the last two years to a point where all foreseeable demands can be met and rationing is no longer necessary.

GG is already available for purchase once again in drug stores for use by physicians in any way they desire. In addition to this source of supply, the Minnesota Department of Health expects to continue a limited program of distribution of globulin to physicians for certain uses, such as the prevention or modification of measles in young children and the protection of household contacts of cases of infectious hepatitis. Globulin has definite value in these conditions. GG that is distributed by the State Department of Health is furnished without charge through the American Red Cross and the National Foundation for Infantile Paralysis, Inc.—*Minnesota's Health,* December, 1954.

LABORATORY CONTROL OF ANTICOAGULANT THERAPY

FRANK D. MANN, M.D.

Rochester, Minnesota

THE USE of the one-stage prothrombin test (Quick prothrombin time) in the control of therapy with anticoagulants of the dicumarol type is an excellent example of the role of the laboratory in modern medicine. In contrast to the screening procedures that occupy much of the time of the clinical laboratory, each prothrombin-time test in the control of anticoagulant therapy provides information specifically required and obtainable in no other way. A number of papers have appeared on this subject; the evidence behind most of these is somewhat less than impressive. Elsewhere I[2,3] have reviewed in some detail the evidence behind the rather strong and dogmatic comments that are to follow.

The prothrombin-time test consists in measurement of the clotting time of plasma on recalcification in the presence of standardized thromboplastin. The test is not merely rapid and convenient, as daily clinical laboratory tests must be, but is also highly accurate when it is properly performed. Nevertheless, unsatisfactory experiences with this test have been reasonably frequent; otherwise there would be no indication for this editorial report. These failures have been due to flagrant disregard of repeatedly emphasized technical principles, some of the more important of which follow:

1. The thromboplastin reagent used must be not only reproducible in its activity with respect to normal plasma but also specifically sensitive to the effect of dicumarol. The principal effect of dicumarol is not on prothrombin but on a substance called the "stable prothrombin conversion factor"; it is this substance and not prothrombin that is measured by the prothrombin-time test when it is properly performed. Retention of the terms "prothrombin time" and "hypoprothrombinemia" to describe the effect of dicumarol is nevertheless inevitable after the years of use of this terminology. The stable prothrombin conversion factor, even in minute amounts, reacts with thromboplastin to form a stable complex (cothromboplastin reaction). Preparations of thromboplastin that have undergone this reaction are specifically insensitive indicators of the effect of dicumarol. At least two such preparations have been offered commercially by means of advertising resembling that extolling certain patent medicines. Since it must be assumed that few clinical laboratories will prepare their own thromboplastin, a step necessary for maximal accuracy, the practical suggestion is offered that no thromboplastin be purchased unless it is specified to be prepared from rabbit brain only, with no added substance whatsoever. It is a sad and rather surprising fact that no commercial manufacturer of thromboplastin ever has seen fit to consult the originator of the prothrombin-time test, Dr. Quick, according to his own statement.

2. The specimen of blood for the prothrombin-time test must be meticulously collected. Incipient coagulation before mixture with oxalate, and likewise an excess of oxalate, must be avoided. The former gives an erroneously short prothrombin time; the latter may cause a false result of incoagulability. It is a good practical rule never to report a prothrombin-time test as showing "no clot" without examining another specimen of blood, since an incorrect report of incoagulability is obviously a serious error. Although one might think that such obvious errors should be rare, ample experience has shown that when specimens of blood are not collected by experienced labora-

---

From the Section of Clinical Pathology, Mayo Clinic and Mayo Foundation.

This is the twenty-third in a series of editorial reports sponsored by the Minnesota Society of Clinical Pathologists and designed to foster closer relationships between clinicians and pathologists.

tory personnel they are often unsuitable for the prothrombin-time test. This probably has been an important factor in unsatisfactory experience with dicumarol therapy in large teaching hospitals in which specimens may be collected by medical students and interns.

3. The apparatus for the test must provide for control of temperature without sacrifice of visibility of the clot, preferably by means of a glass water bath. The light should be adjustable to the maximal advantage of the technician. There also must be a means of accurate measurement of the clotting time, preferably an electric stop clock operated by a foot pedal, which leaves the hands free for the necessary manipulation of pipet and test tube. Elaborate water baths that do not allow a good view of the clotting process and photoelectric apparatus that hampers the rapid addition of reagents and the control of temperature are not improvements.

4. Perhaps most important of all, the test must be performed by a person properly grounded in laboratory discipline who has had sufficient practice with this specific test under supervision. Such a person must be allowed to perform the test with reasonable freedom from interruption. Coagulation tests, involving precise timing, are peculiarly susceptible to error due to interruptions, such as the innumerable telephone calls that many clinical laboratories receive. Far too often, errors are attributed to basic inadequacies of technique when they are actually due to impossible working conditions.

Dogmatism will not be carried so far as to specify the precise version of the Quick prothrombin test that should be followed; reference is made to a technique that has given excellent results over a fifteen-year period.[1] Several other versions appear to have given good results but no modifications or gadgets are likely to circumvent the basic laboratory requirements with respect to reagents, specimens, apparatus, personnel and time.

This brief account is concerned only with the laboratory techniques involved in the control of anticoagulant therapy, not with the therapy itself. It may properly be noted, however, that the originators of such therapeutic methods emphasized from the outset the absolute necessity of precise laboratory control. It is thus surprising that authors who have condemned anticoagulant therapy as hazardous often have failed to mention how they performed the prothrombin-time test or even have stated that due to lack of technical personnel they were unable to perform this test accurately. This attitude resembles that of a surgeon who would condemn the operation of cholecystectomy on the basis of a series of strictures of the common bile duct.

EARNINGS OF REHABILITATED VETERANS

Disabled veterans rehabilitated under a special VA training program have more than doubled their pre-war incomes. This is one of the findings of a follow-up survey conducted by the Veterans Administration. It shows that before service the men averaged $32 a week, but after the special training, they averaged $72 a week. In the postwar years, the average pay of all non-veterans went up 19 per cent, that of able-bodied veterans 50 per cent, but the average veteran who completed the special training increased his earnings 75 per cent in this period. Medical education was one of the fields where the veterans had a high rate of rehabilitation, 76 per cent. Medical disabilities of the veterans surveyed were classified as follows: orthopedic 41 per cent, nervous or mental 24 per cent, circulatory and heart 7 per cent, and tuberculosis or other respiratory 8 per cent.

The special training is restricted to service-connected cases where the disability has or could seriously interfere with the veteran's employment in his established occupation. Training is limited to four years. The average in the group studied twenty-one months.

"I'M NOT MARRYING YOUR MOTHER"

Well, maybe you aren't marrying your future spouse's mother, but you might almost as well be. And except for the less certainty about paternity, you might almost as well be marrying the (apparent) father, too. Setting aside all the personal characteristics that your spouse might acquire from parents via merely growing up with them, the Metropolitan Life Insurance Company's *Statistical Bulletin* for September, 1954, points out in its lead article on "Family History and Longevity" the following interesting facts.

The mortality among 15,000 policyholders who had two or more close relatives with cardiovascular-renal disease acquired before age sixty, was about 40 per cent higher than for standard ordinary risks as a whole. Most of the excess mortality was from diseases of the heart and vascular system.

In two large companies, among insured who, in addition to having a family history of cardiovascular-renal disease, either were slightly over weight or had a slight elevation in blood pressure, the mortality was 70 per cent higher than the average for ordinary standard risks.

The work of Dr. May Wilson and her associates in New York City indicates an hereditary susceptibility to rheumatic fever and rheumatic heart disease.

The prevalence of coronary heart disease was considerably higher among the parents of a group of young people suffering from coronary heart disease than it was among parents in a control group.

In policyholders reporting two or more cases of cancer in parents or siblings under age sixty, the mortality from all causes was about average, *but* the mortality from cancer, which accounted for one-third of all the deaths in this group, was more than twice the average.

The mortality from diabetes among policyholders with even a single diabetic person (at any age) in the family was nearly twice the average for all standard ordinary policyholders.

The mortality from suicide was several times the normal in insured persons who reported two or more cases of mental disease in the family before the age sixty (the age limitation serves to eliminate most cases of mental disease or degeneration due to cerebral arteriosclerosis).

Persons with a good family history of longevity, live longer on the average than those with a poor record of parental longevity.

All of which would make us amend the advice to choose a spouse with good health, intelligence, and a good sense of humor, by the addition of similar specifications for the spouse's parents.

H.G.M.

LIFE INSURANCE APPLICANT EXAMINATIONS

With more than 70 million Americans now owning life insurance and with hundreds of thousands of applicants being considered each year, the life insurance medical examiner has become a key figure in the largest American business enterprise outside the U. S. Government itself.

The wonder of it all is that in such a tremendous mass operation—involving printed forms, special rules and routines, and a multitude of personalities—the job of qualifying applicants for life insurance goes as smoothly as it does, with irritation and inconvenience to the examining doctor occurring only in relatively rare cases.

Consider some of the elements involved. There are forms to be filled out—fairly complex forms because the information desired usually relates to what will be a lifetime transaction, often involving many thousands of dollars. There are routines to follow which may on occasion seem a nuisance to the examiner unfamiliar with life insurance home office procedures. And lastly, there are personalities to be dealt with, not the least of which may be the applicant who, because he presumes himself to be healthy, does not always feel the same compulsion to co-operate as he would if he were seeking medical counsel in the usual doctor-patient relationship.

The fact, then, that these vast numbers of examinations are conducted so smoothly and successfully is, to a considerable extent, a tribute to the American physician's co-operation in expediting a social service which is of the broadest significance to modern-day Americans—doctors included.

The purpose of the life insurance examination is to obtain objective criteria which can be applied to the laws of actuarial and underwriting science. It is by no means a complete evaluation of the applicant's physical condition; this obviously would be too costly. But by establishing a minimum number of objective criteria such as the level of blood pressure, heart rate, height, weight, et cetera, definite objective or dollar and cents evaluation can be placed on the prospects for the individual's longevity. Actuarial and underwriting science is amazingly precise, even using as facts such variables as physical findings.

Relatively meager though these facts are, the industry has been able to set up a system of evaluating longevity which has proven very accurate. And since these facts are the whole basis for action, they must be accurately determined. The examinations in many cases have uncovered medical impairments of which the applicant was unaware, and have prompted him to seek medical help for these impairments.

The questionnaire which the physican is asked to fill out covers not only results of the examination, but the medical history of the applicant and his family, as certified to by the applicant. Some of these questions may strike the physician as reaching far afield, but each is designed to bring out some aspect of the record which the company, on the basis of its experience, deems relevant. An active committee of medical directors has as its sole purpose the elimination of unnecessary questions from the medical blank, and from the standpoint of the industry, these blanks have been materially shortened in recent years.

Unfortunately, because of the size of the industry, both applicant and physician must conform to a set routine. However, because of the importance of the examinations, and recognizing that the facts the doctors are attempting to establish are much better obtained in the doctors' offices, the companies prefer and do all in their power to see that these examinations are made at the doctors' offices.

It would be impossible to act impartially on the large number of cases handled each year if the company solicited the personal judgment of the physician. Medical underwriting depends on impartial facts, and cannot take into consideration the most interesting part of medicine—the *art* of medicine. The physician cannot be expected to decline or rate the applicant. It is his function to furnish the facts, and let the underwriters use these facts to determine the rating. This impersonal relationship has proven to be the only practical and equitable way of determining the necessary facts.

With hundreds of thousands of applicants reviewed each year, insurance "medicals" are a source of significant income to the medical profession. Currently, the life insurance companies are paying the doctors of the country about 17.5 millions a year for these examinations, with the level at which fees are fixed closely related to usual charges for comparable work.

As a result of this continuous co-operation by the medical profession, the insured mortality of the companies has been progressively improving, and this in turn has allowed the life insurance companies to hold the cost of life insurance protection to the American public at a far lower level than would otherwise be possible.

Karl W. Anderson, M.D.

RADIO-ISOTOPES IN MEDICINE

Although the advent of artificial radio-isotopes has had its principal impact on research, certain applications are emerging which are useful in the practice of medicine, both diagnostically and therapeutically. So far, there are four isotopes which stand out in this respect; namely, I-131, P-32, Au-198, and Co-60.

Diagnostically, the radioisotopes are employed as "tracers." For example, the avidity of the thyroid gland for iodine, a property directly related to thyroid function, is determined by administering orally a tiny quantity of radio-active iodine and then measuring with a Geiger counter after a certain number of hours the percentage of this I-131 which has been taken up by the thyroid gland. Similarly, the blood volume can be determined by injecting a small quantity of an appropriate radio-isotope into the blood stream, allowing time for mixing, and then withdrawing and measuring a sample to determine the dilution factor. Radio-isotope tracer techniques have the advantage of simplicity and increased accuracy over some of the alternative chemical and colorimetric methods.

The usefulness of thyroid uptake studies with I-131 is not limited to large institutions and city practice. This method is applicable to small scale practice also, and various rural hospitals and clinics are profiting from its contribution to the accurate diagnoses of thyroid aberration.

Therapeutically, radio-isotopes fall in the field of radiation therapy, and permit a wide range of applications, sometimes involving an intimate role in metabolic processes, as when P-32 is used to treat polycythemia vera, and I-131 to treat Grave's disease. Radioactive gold (Au-198) holds promise in the palliation of selected cases of carcinomatous effusions in the abdominal and pleural cavities. Co-60 has many of the properties of radium as well as certain advantages over it and is being used as needle sources as well as in large radiation units for the treatment of malignancy in thick portions of the body.

Thanks to the pioneering experience of the last sixty years in the hazards of radiation, numerous safeguards have now being instituted so that work with radio-isotopes can be a completely safe procedure.

Elmer C. Paulson, M.D.

THE SAVINGS AND LOAN INVESTMENT

What is the value to a doctor's estate of an investment in savings and loan associations? The answer is quite simple. No other investment of equal safety and liquidity pays such a high return. Let's look at those three key points in order: safety, liquidity and high return.

From a safety standpoint, you're on solid ground with an investment in insured savings and loan associations. You are investing in families and homes, the very backbone of America. Basically, the business of the savings and loan industry is that of making mortgage loans on single-family, owner-occupied homes. Financial history proves that those are blue-chip risks. They meet the most important safety requirement of a good investment program—diversification. The incomes of families buying homes are derived from hundreds of different businesses, services and professions. Your investment in savings and loan associations, in other words, is backed by all or most of the business activity in an entire metropolitan area.

In addition to the safety factors inherent in a savings and loan investment, your account at any federally chartered association is insured for safety up to $10,000 by the Federal Savings and Loan Insurance Corporation. This insurance is automatic without charge to you.

Turning to the factor of liquidity, or availability of your money, it has long been the custom of savings and loan associations in metropolitan areas to pay withdrawals promptly on request. Larger associations, in particular, ordinarily maintain a high degree of liquidity with a strong percentage of their assets in cash and government bonds. In addition, there is a constant flow of new cash into each association as a result of new savings accounts, monthly interest payments on loans and monthly repayments of the principal on mortgages.

This brings us to the important point of high return. Look back through the years and you'll find that savings and loan associations have always paid generous dividends. In the Twin Cities, they currently are paying investors an annual rate of 3 per cent compounded semi-annually. To earn a higher rate of return, you'd have to move into an investment area that may sacrifice safety.

Let us look briefly now at two other advantages of investing in savings and loan associations. It requiries no management expense, worry or bother, such as is involved in owning stocks or bonds and many other investments. And your savings and loan investment is not subject to fluctuations in principal value as is the bond and stock.

Basically, the savings and loan investment is valuable to your estate because it pays a higher return than is available on other investments of equal safety, liquidity and convenience.

Roy W. Larson

President, Twin City Federal Savings and Loan Association

CORRECTION

In the October, 1954, issue of Minnesota Medicine, an error occurred in the paper by Matthew A. Kiess, O.S.B., Ph.D., Robert P. Koenig, M.D., and Clifford R. Myre, M.D., entitled "Development of a Simplified Filter Paper Electrophoresis with a Study of Human Serum Proteins." Line eight, column two, page 709, should read ". . . and *15 grams* of sodium diethyl barbiturate . . ."

President's Letter

THE ANNUAL CHALLENGE

The beginning of a new year, and all that traditionally goes with it, has turned out to be a challenge of major proportions in the year 1955.

Every year we find ourselves confronted with the dilemma of feeling obliged to make a certain number of New Year's resolutions—which we immediately break with equally resolute rationalization. What we need is the fortitude and determination to either keep every resolution we make, or to so live that it will be unnecessary to make resolutions in the first place.

But seriously, New Year's resolutions have a proper place in our lives today. We take a backward and a forward look at this time of year—we analyze where we stumbled in the past year, and decide firmly not to stumble over the same things in the coming year. And thus, we grow in stature, in experience and in better living.

We as physicians, however, find that January 1 is not the only time we must firmly resolve. Throughout every month of every year we are constantly challenged by some new problem which requires a quick, and correct, decision on our part. With every new patient, with every new medical organization problem, with every new medical-economic concept, we meet a challenge to maintain the tradition of public service which has been our American heritage.

Because the above tasks seem never ending, there is a tendency to become discouraged and lackadaisical in our efforts. Let us realize that it is a privilege to serve, and the simplest and most effective way to attain our ends is for each of us to strive diligently to make our lives as close to the ideal of medical practice as possible.

As your new president, I hope to take over the duties with a humble and dedicated heart. I pledge to work for Medicine and its high ideals; with the good will and willing co-operation of all conscientious members of the Association, I feel that we can continue to maintain and improve the high plane of practice we have known in Minnesota through the years.

To say that I am proud of our organization is somewhat of an understatement, for this group has been a strong and valiant one in the state. It has constantly stood for right; it has fought hard for its position of leadership; it has been headed by some of the finest people in the profession. With such standards to follow and uphold, it will be a great challenge to your president. But I hereby resolve to serve my term as president to the best of my ability; and I pray that, with your valuable assistance, I shall not break that resolution.

Arnold O. Swenson

President, Minnesota State Medical Association

The Dean's Page

I would like to take this opportunity to say a few words to the physicians of Minnesota concerning the requests which the Regents of the University will present to the 1955 Legislature for the support of the Medical School and University Hospitals.

The basic support of the Medical School—that is, faculty and technical staff salaries, supplies and expenses, library, heat, light, custodial service and maintenance of Medical School buildings—is included in the general University maintenance request for $17,262,846 for each year of the 1955-57 biennium. This includes $771,423 for promotions and for a 7.5 per cent increase in faculty salaries to partially meet increases in living costs which have occurred over the past two years: $391,647 for increases in Civil Service salaries, 6.9 per cent, in accord with the State Civil Service pattern; and $707,719 for new faculty positions to take care of increasing enrollments and other service responsibilities.

The University Hospital request is a "special" of $1,100,000 for the first year of the biennium and $1,125,000 for the second year of the biennium. This really represents an authorization to the state treasurer to reimburse the University for one half of the bills of "county patients" up to a maximum of this amount. Incidentally, the annual appropriation requested is $155,736 less for the first year and $130,736 less for the second year than for the year 1954-55.

Other "specials" for each year of the biennium include $75,000 for general medical research, $15,000 for the human aspects of brucellosis, $15,000 for continuation of the Multiple Sclerosis Clinic, $469,966 for the Psychopathic Hospital, $166,000 for Child Psychiatry, and $278,345 for the Rehabilitation Center. There is no matching of state funds by counties for patients in psychiatry, child psychiatry, or rehabilitation.

For building the Regents are requesting three appropriations that are vitally important to the Medical School. These are as follows: for remodelling of Millard Hall $330,000; for the Medical-Biological Library $875,000; for the remodelling of the University Hospitals and for needed equipment of the Hospital and Mayo Memorial $1,000,000.

The remodelling of Millard Hall, which was constructed more than forty years ago, has been long overdue but has been postponed until some of the departments that were previously housed in that building could be moved into the Mayo Memorial. This remodelling is a "must" if the laboratories in this building are to be used by the Departments of Physiology, Physiological Chemistry, and Pharmacology that will continue to occupy this building.

The Medical-Biological Library was listed almost twenty years ago by the students and faculty as the most critical need of the Medical School. The University of Minnesota has a splendid medical library, but since it has been housed in the Main Library Building, three or four blocks from the Medical School and Hospital, its use has been minimal. In the plans for the Mayo Memorial two floors were to be devoted to the Medical Library. However, the inflation and increased building costs which occurred as a result of the war in Korea necessitated the elimination of eight floors, including the library, from the tower portion of this building. The Medical Library was then placed on the University's list of buildings requested from the 1953 Legislature, but with appropriations at this session for a new law library building and for a library building on the Duluth Campus, the Medical Library was passed over.

A most important aspect of modern medical education is to develop in medical students the habit of intelligent and discriminating reading of medical literature as a basis for keeping abreast of medical developments throughout their years of

George Earl, M.D., Chairman

FEDERAL HEALTH BUDGET TO REACH OVER $2 BILLION

The federal government this fiscal year (July 1954-June 1955) is spending an estimated $2,141,681,661 for its health, medical and related activities, which range from construction of multi-million dollar hospitals to maintenance of clinics, according to a recent issue of the AMA Washington letter.

The programs are spread among more than a score of departments, independent agencies, and commissions. This total figure means:

1. It is 8 per cent more than $1,775,882,000 budgeted by the federal government last year for the same purpose. (The 8 per cent overall increase does not include that part—70 per cent—of the Defense medical budget increase that the department estimates is chargeable to operating and construction costs, items not available last year under the accounting procedure then in use.)

2. It is equivalent to 10 per cent of the $22,000,000,000 that represents the entire U. S. budget with defense security costs eliminated.

3. It is approximately one-sixth of all the money spent in any way for medical and health items in this country annually, including the cost of drugs, dental care, pharmaceutical items, and drug store sundries. (Department of Commerce estimates the total U. S. health bill at $12,000,000,000.)

Departmental Breakdown

Breaking down the total figure by departments and their individual health and medical budgets, the following figures come to light:

Department of Defense—this year: $845,487,500; last year: $533,311,000. Department of Health, Education and Welfare—this year: $395,754,000; last year: $340,553,000. Federal Civil Defense Administration—this year: $28,755,000; last year: $26,650,000. Department of Interior—this year: $28,023,498; last year: $27,258,600. Atomic Energy Commission—this year: $27,000,000; last year: $26,565,000. Department of Labor—this year: $6,811,000; last year: $8,960,000. Federal Employes Health Program—this year: approximately $6,000,000; last year: approximately $6,000,000. Federal Trade Commission—this year: approximately $1,000,000; last year: approximately $1,000,000. Commission on Intergovernmental Relations—this year: $414,000; last year: $500,000. Civil Service Commission—this year: approximately $358,000; last year: new item. Department of Commerce—this year: $278,133; last year: $621,000. Veterans Administration—this year: $748,738,563; last year: $747,415,264. Department of State—this year: $12,607,667; last year: $14,127,733. Foreign Operations Administration—this year: $25,574,300; last year: $24,500,000. Panama Canal Zone—this year: $5,600,000; last year: $5,448,600. National Science Foundation—this year: $4,795,000; last year: $8,000,000. Department of Treasury—this year: $2,770,000; last year: $2,790,000. Department of Justice—this year: $1,300,000; last year: $1,326,000. National Advisory Committee to Selective Service—this year: $190,000; last year: $265,000. Commission on Organization of Executive Branch of Government—this year: approximately $130,000; last year: $500,000. Health Resources Advisory Committee—this year: approximately $95,000; last year: $91,000.

JAMA ASKS TAX-SUPPORTED MEDICAL SCHOOLS RELAX RESTRICTIONS

A recent issue of *The Journal of the American Medical Association* has recommended that state and city medical schools should relax their restrictions on admitting students from limited geographical areas.

An editorial in *The Journal* states that such limitations represent "a shortsighted policy that is a disservice to both the state and the school." The article goes on:

> "With roughly one-third as many applicants per vacancy to choose from as the other schools, the tax-supported schools are often placed in the unfortunate situation of having to select inferior applicants or fail to fill their quota."

With continually improved methods of screening candidates, *The Journal* says, the nation's medical schools have sharply cut the rate of students who drop out—largely because of academic failure—before graduation. This attrition rate dropped from 9.4 per cent in the freshman year 15 years ago to 5.1 per cent in 1952-53. Senior year attrition was only 0.2 per cent that year.

The article concludes: "As a result of being forced into unwise selections these (city and state) schools have an attrition rate twice that of schools that are free to select students without reference to their state residence. . . . If state and city schools would relax their restrictions even to the point of choosing a certain percentage of their students from other areas (at a slightly higher rate of tuition and with a certain amount of reciprocity) this would have a salutary effect."

AMEF REPORTS STATE STANDINGS

A recent report from the American Medical Education Foundation reveals the individual state standings in regard to reaching annual contribution goals to the Foundation.

The Foundation reports:

> "In over-all income and contributors, the Foundation is ahead of last year's totals. However, we are still short of the estimated $1,200,000 income figure that was projected earlier this year. We have received a total of $1,051,000 from more than 17,000 contributors. Since we did not pass the million dollar mark until late in November last year, we are ahead in our income record of last year by about 30 days. In short, we have an estimated 30 days to surpass our 1953 record."

The above statement was made early in November, and the bulletin was issued in an effort to pass the goal before the end of 1954.

State Contributions

Summarizing individual state achievements in this vital field of aiding medical education, the Foundation stated that during the first ten months of 1954, six states exceeded their 1953 marks in both dollars raised and contributors. Four other states increased their dollar income over 1953 but have not exceeded their total number of contributors. Five states exceeded totals in the number of contributors but not their dollar income over the previous year. Two states remained even with their 1953 records.

It is disappointing to note that Minnesota is not on any of these lists. However, Minnesota physicians have an opportunity to begin 1955 with a new and better record. The importance of making contributions to this fund cannot be overemphasized, for it has been one of American medicine's greatest weapons against federal subsidies for medical schools, which threatens federal control. It is also noted that considerable tax saving is realized by contributing to this fund.

PRESIDENT CITED FOR MEDICAL EDUCATION WORK

For his demonstrated interest in medical schools, and his efforts to bring them financial support from non-governmental sources, President Eisenhower has been honored with the first Frank H. Lahey award. While he was president of Columbia, Mr. Eisenhower was largely responsible for getting the National Fund for Medical Education under way. This fund collects money from non-government sources for distribution to medical schools "with no strings attached."

The Lahey award is a memorial to the late Dr. Lahey of Boston, past president of the AMA, who was a leader in the movement to keep medical schools solvent without federal aid. The presentation was made at the White House by S. Sloan Colt of New York, president of the National Fund for Medical Education. It was sponsored by the American Medical Association and the Association of American Medical Colleges, as well as the National Fund Organization.

In accepting the award, the President said he believes medicine "is one profession we don't want to get under the dead hand of bureaucracy." He said:

> "Quite naturally, I am very proud to receive an award from such an Association, from such a group. There is

an added distinction because it bears the name of one of our greatest professionals and our greatest citizens. On the other hand, Mr. Colt, I rarely felt quite so unworthy of receiving an award because my part in the organization of this National Fund was really getting someone else to do the work. It would be far more fitting this morning if I were presenting this to you, because you have been President of the Association from the beginning. But I can say this: I don't know of any group that is doing more necessary and worthwhile work than making certain that our medical schools have ample funds from private sources to keep running, because this is one profession we don't want to get under the dead hand of bureaucracy."

REINSURANCE TO BE REINTRODUCED

President Eisenhower has announced that he definitely plans to resubmit his health reinsurance plan to the next Congress, in spite of widespread opposition, not only from the AMA, but from much of the insurance industry, the U. S. Chamber of Commerce and many other groups.

In announcing his intentions not too long ago, the President said it would be "an important part of the health program in the great gaps in the field of health," adding that "we are years behind our potential achievement in the availability and adequacy of health services."

Mrs. Hobby, secretary of HEW, when reiterating the President's plan to resubmit the program, was asked about AMA's opposition and stated, "I very much hope that the AMA will see its way clear to support health reinsurance. We have the same objectives, the difference is only one of method." Incidentally, no additional pronouncement of policy on this matter was forthcoming from the Clinical Session of the AMA in Miami in December. Speculation was abroad whether or not the AMA may possibly have changed its mind on its opposition to reinsurance.

LABOR SECRETARY URGES EXPANSION OF HEALTH INSURANCE

Secretary of Labor Joseph P. Mitchell, joining in the public discussion of the administration's health and medical goals, advocates extension of health plans and continued development of medical education. According to a recent issue of the AMA Washington Letter, Mr. Mitchell made his statements in an address to the anniversary dinner of the Health Insurance Plan of Greater New York (HIP).

The Secretary said that great strides have been made in voluntary health insurance, providing "some degree of protection" to American families, but "much less has been done in terms of comprehensive health programs which provide complete medical and surgical care in the hospital and home."

Mr. Mitchell went on to say that there is no doubt in his mind that the American people are determined "to proceed on all fronts to establish adequate systems of health insurance."

Praises HIP

He also described HIP as "a good example of the development of a comprehensive system of medical care and hospitalization through a form of pre-payment which can be met by the average family." And, in addition to the widest possible medical care at the lowest possible cost, the country must have an adequate number of physicians, nurses and technicians as well as adequate hospitals, laboratories and medical research centers, Mr. Mitchell noted.

LARGE DOCTOR DRAFT CALL

More than twice the number of men taken in the last Doctor Draft call will be tapped for April induction, the Defense Department announces. This is presumably the last medical officer call under the present Doctor Draft Act, which is scheduled to expire on June 30, 1955. The Defense Department has asked Selective Service for 1,275 physicians—825 for the Army, 200 for the Navy, and 250 for the Air Force—and 459 dentists for the three-month period starting next April. The last quarterly Doctor Draft call, issued for December, 1954, took 550 physicians and 150 dentists. Priority III men (doctors not educated at government expense who have served no time on active duty) will comprise the majority of those taken in April.

Public Health

TRIBUTE TO TWO PUBLIC HEALTH WORKERS

Public health in Minnesota experienced an irreparable loss in the recent death of two women who spent their lives in devoted service to the people of this state. The Minnesota Department of Health desires to pay tribute in this section of MINNESOTA MEDICINE to the memory of Mrs. Kathryne R. Pearce and Miss Ann S. Nyquist. Mrs. Pearce, executive secretary of the Hennepin County Tuberculosis Association, died November 27, 1954, at the age of fifty-six years. Miss Nyquist, chief of the Section of Public Health Nursing for the Minnesota Department of Health, died December 8, 1954, at the age of sixty-six.

Mrs. Pearce was the wife of Naboth O. Pearce, M.D., until recently director of the Chronic Diseases and Geriatrics program of the State Health Department. Her work with the Tuberculosis Association began in 1918, when she was graduated from the University of Minnesota School of Social Work. She served as executive secretary of the Association for thirty-two years, from 1922 until her death in 1954. She was an officer or member of all Hennepin County organizations concerned with tuberculosis control, including the health council, the Tuberculosis Administrators, and Trudeau Society, and the Minnesota Rehabilitation Association. For twenty years, she served as member or chairman of the Committee on Rehabilitation of the National Tuberculosis Association, and in 1932 was president of the National Conference of Tuberculosis Workers.

The Board of Directors of the Association said of Mrs. Pearce:

> "Under her sincere and able direction, the Association's work has not only been responsible for saving many lives in Hennepin County, but it has served as a pattern, in many instances, for tuberculosis control measures throughout the nation. She was deeply concerned with the return of the tuberculosis patient to normal living and self-support. She helped to establish the national pattern for the rehabilitation of the tuberculous, making training for a future job a part of the treatment. She was alert to the many special problems of the tuberculous patient and his family—emotional and economic—and, to help solve these problems, worked with many individuals and groups in the community. The nation's fight against tuberculosis is proof of what consistent effort and hard work can accomplish. She was such a worker."

Ann Nyquist, too, spent her entire adult life in public service. Born in Renville County, Minnesota, she took her nurses training at St. Barnabas Hospital, Minneapolis. She was graduated in 1915 and served for the next three years there as anesthetist. During World War I, she served in a similar capacity at Base Hospital 26 in France. On her return, she studied public health nursing at the University of Minnesota, completing her course in 1920. Her first public health assignment was with the Red Cross in Sherburne County. Later, she served as public health nurse in Renville County.

In 1925, Miss Nyquist joined the Minnesota Department of Health as advisory nurse. In this position, her duties consisted of field supervision of local nurses and promotional work in the development of public health nursing services in Minnesota counties. In 1941, she was apointed director of public health nursing, a position she held until her death.

During World War II, she served as chairman of the Minnesota Procurement and Assignment Service for Nurses. In 1946, she received a citation signed by President Harry S. Truman "in recognition of uncompensated service to the United States of America during World War II." The citation reads: "She served with diligence and distinction in the interests of meeting both military and civilian needs . . . for the successful solution of complex and imperative wartime problems." In the same year she received a similar citation from the American National Red Cross.

In 1949, the Minnesota Department of Health, with the co-operation of the Hennepin County Tuberculosis Association and the Minnesota Division, American Cancer Society, produced the film, *Your Friend in Blue*. This film, portraying the work of a public health nurse, was dedicated "To a pioneer Minnesota public health nurse, Ann S. Nyquist." The film has been widely shown throughout the United States and has been used by the Voice of America.

Miss Nyquist had many public health interests. Among the chief were the Indian health program, rehabilitation of the disabled, meeting the needs of retarded children, and advancing the professional status of public health nurses. She was active in both the national and state League for Nursing, and during the last week of her life organized a fund drive for that group.

Current Cardiac Concepts

DIAGNOSIS OF CORONARY HEART DISEASE

With the increasing recognition of the prevalence of coronary arteriosclerosis, doctors have become increasingly cognizant of the shortcomings of currently used diagnostic procedures. Obvious cases are readily recognized by their characteristic symptomatology and/or their specific electrocardiographic abnormalities. The electrocardiogram need not, however, be abnormal, and many cases show normal electrocardiographic pattern. Careful physical examination may disclose no abnormalities. Asymptomatic cases are, therefore, seldom recognized unless special diagnostic tests are made routinely or are indicated by certain non-specific abnormalities detected on routine physical examination.

There remain, nevertheless, many cases in which both clinical history and special diagnostic procedures are normal, and consequently, the clinical diagnosis of arteriosclerotic heart disease cannot possibly be made. It is this silent case that defies all known methods of detection which is an enigma to the physician. How often, unfortunately, is a patient given a "clean bill of health" only to have, subsequently, an acute myocardial infarction or, worse yet, to die suddenly from coronary heart disease which obviously was present at the time of the "negative" examination? It is because of this that one must be cautious to carefully evaluate vague, but suggestive, symptoms when they appear to plague one's diagnostic acumen.

On the other hand, it is equally important that the physician not be misled by a patient's vague chest symptoms into making a diagnosis of heart disease which does not exist. Important as it may be to make the cardiac patient aware of his disease and to teach him how to best protect himself, insofar as is possible, from its complications, so is it equally important to assure the patient who has no such disease that his symptoms are not cardiac in origin. No greater injustice can be done the individual with a normal heart than to mistakenly tell him he has heart disease, thereby coloring all his future actions and thoughts with the fear of imminent and unpredictable happenings. Few among us could accept with equanimity the diagnosis of coronary heart disease with all its implications; yet few among us would want *not* to be informed of its presence so that any prophylactic measures of value could be instituted. It is therefore of extreme urgency that the diagnosis, negative or positive, be as accurate as possible.

It is the presence of pain in any of the locations wherein heart pain may occur which usually raises the question of the possible presence of coronary heart disease. The clinical picture and electrocardiographic evolution seen in typical acute myocardial infarction *usually* make this diagnosis relatively simple, and other diseases with similar clinical symptoms are excluded with relative ease. On the other hand, with the shorter and generally milder pain of transitory coronary insufficiency (angina pectoris) the proper evaluation may be more difficult. *No* laboratory aid is as important in making this diagnosis as is a carefully elicited history. The location, character and radiation of the pain are often of help, but most important is the fact that this pain is resultant upon exertion (physical or emotional) and that it subsides promptly with rest or with nitroglycerine (although the latter occasionally relieves non-cardiac pains of smooth muscle origin). This pain does not generally occur at rest (except with myocardial infarction), and the fact that it is more easily precipitated after eating or on a cold or windy day is important diagnostically.

The reproduction of the pain or the production of electrocardiographic changes by the inhalation of oxygen poor air mixtures or the Master Two Step Test is of inestimable aid diagnostically if the result is positive. A negative test certainly does not exclude arteriosclerotic heart disease.

In recent years much study has been devoted to understanding the relationship of coronary heart disease to serum lipids in general and to serum cholesterol more specifically. Although research workers agree that the two are intimately related, this relationship is not yet clarified, and the level of serum lipids cannot be used diagnostically. Tests based on the relationship of the amounts of one type of lipid to another or on lipid patterns as determined by ultracentrifugation have not proved uniformly reliable. Authenticated cases of coronary heart disease with normal lipid amounts and proportions occur commonly.

It is entirely conceivable that someday a chemical or electrocardiographic test will be devised to detect the cases of "silent" coronary heart disease. There is also an increasing awareness of an apparent hormonal factor, and a diagnostic test along such lines may be forthcoming. In any event, no single consistently accurate test is now available, and it is on the carefully elicited and clearly evaluated clinical history that one must

AMERICAN MEDICAL ASSOCIATION

Proceedings of the House of Delegates

EIGHTH CLINICAL MEETING

November 29 to December 2, 1954

Miami, Florida

Geriatrics, medical ethics, internships, grievance committees, hospital accreditation, osteopathy, the doctor draft law, state-subsidized medicine and malpractice insurance problems were among the major subjects of discussion and action by the House of Delegates at the American Medical Association's Eighth Clinical Meeting held November 29-December 2 in Miami.

During the meeting the AMA Board of Trustees also announced the appointment of a thirteen-member Commission to make a comprehensive survey of the various types of plans through which the American people receive medical services. The Commission, headed by Dr. Leonard W. Larson of Bismarck, North Dakota, member of the Board of Trustees, will begin work immediately and will require at least a year to complete its survey.

Named as the 1954 General Practitioner of the Year was Dr. Karl B. Pace of Greenville, North Carolina, whose selection by a special committee of the Board of Trustees was announced at the opening session of the House of Delegates on Monday by Dr. Dwight H. Murray of Napa, California, Board Chairman. Dr. Pace received the medal and citation, presented annually for community service by a family doctor, from Dr. Walter B. Martin of Norfolk, Virginia, President of the American Medical Association, immediately after the announcement.

Other highlights of the opening session were addresses by Dr. Martin; Seaborn P. Collins, National Commander of the American Legion; Mrs. Oveta Culp Hobby, Secretary of Health, Education and Welfare; Edwin J. Faulkner, President of the Woodmen Accident and Life Company of Lincoln, Nebraska.

Mr. Collins told the House that he is willing to appoint qualified Legion representatives on a committee to take part in joint Legion-AMA study of veterans' hospitalization. Later during the meeting the Board of Trustees announced appointment of a three-man committee to meet with the Legion on the issue of veterans' medical care. The members of the AMA committee are Dr. Elmer Hess, Dr. David Allman and Dr. Louis Orr.

Registration toward the end of the third day of the Clinical Meeting included 3,167 physicians; 3,441 guests including residents, interns, nurses and others, and approximately 900 exhibitors and exhibitors' guests—for a grand total of more than 7,500. Final total registration at the 1953 Clinical Meeting in St. Louis was 7,716.

New AMA Geriatrics Unit

The House of Delegates passed a Pennsylvania resolution which directed that the AMA Board of Trustees "consider the creation of an organization on geriatrics within the present structure of the American Medical Association, the purpose of which shall be (1) to develop and assist committees on geriatrics and gerontology originating from constituent state associations and component county societies of the American Medical Association; (2) to act as a liaison between such state and county committees so there shall be a free flow of information between all levels of organized medicine on the subject of geriatrics; (3) to make available to the American people such facts, data and opinions concerning the subject of geriatrics as may be considered of value in alleviating social and medical problems created by the increasing population of older age groups; and (4) to perform such other duties as will improve and advance the medical care rendered to people of the older age group."

Medical Ethics

Accepting a recommendation in a report of the Council on Constitution and Bylaws, the House amended Section 7 of Chapter I of the Principles of Medical Ethics so that it now reads as follows on the subject of patents and copyrights:

> "A physician may patent surgical instruments, appliances and medicines or copyright publications, methods and procedures. The use of such patents or copyrights or the receipt of remuneration from them which retards or inhibits research or restricts the benefits derivable therefrom is unethical."

In another action involving medical ethics, the House rejected a Kansas resolution which would have removed Section 8 of Chapter I from the Principles of Medical Ethics. The Reference Committee on Miscellaneous Business, in recommending disapproval of the resolution, said:

> "The American Medical Association would fail to assume a vital responsibility if no provision is included in the Principles of Medical Ethics regarding the problem of ownership of drug stores and dispensing of drugs by physicians. . . . It is possible that some phases of this principle are susceptible of amendment or change, but certainly the entire principle should not be discarded."

Report on Internships

Acting on the report of the Ad Hoc Committee on Internships, the House accepted a recommendation of the Reference Committee on Medical Education and Hospitals that "the data and judgments of the Ad Hoc Committee on Internships will provide valuable guidance to the Council on Medical Education and Hospitals and with this in view it is recommended that the report be referred to the latter for their further study and guidance." Following are a few excerpts from the report of the Ad Hoc Committee on Internships:

"It is our opinion that graduates of foreign medical schools should be considered for intern appointment in approved hospitals only when there is satisfactory evidence that:

"1. Language difficulties will not seriously impair the program.

"2. The same educational standards are applied to graduates of foreign schools as to graduates of approved American medical colleges.

"3. The appropriate state licensing board approves. . . .

"The Committee believes that the present standards detailing only the number of annual admissions, autopsy rate, number of beds and assignment of an intern to from 15 to 25 beds, are without significant meaning unless and until every local situation is reviewed 'on the grounds' and with full opportunity for discussion between the representative of the accrediting body and representatives of the hospital's governing board and its medical staff. . . .

"Had the 'two-thirds rule' remained a requirement and been rigidly applied to the two consecutive intern years 1952-3 in combination with 1953-4 it would have removed 448 hospitals, cancelled 4,205 internships to which 784 students were matched in those years and reduced the number of internships available to 6,766. . . .

"The committee suggests consideration of some requirement based on filling a percentage of approved internships and a time limit to eliminate some of the unhealthy aspects of the present situation. The following requirement is recommended: Any internship program which in two successive years does not obtain one-fourth of its stated intern complement be disapproved for internship training.

"As applied to the figures for 1952-3 in combination with 1953-4, this requirement would have removed 277 hospitals, cancelled 2,139 internships to which 80 students were matched in those years and reduced the number of internships available to 8,832."

Grievance Committees

In order to improve efficiency and maintain high standards in the operation of grievance or mediation committees, the House endorsed the principles of two similar resolutions introduced by the Colorado and Mississippi delegations and asked the Board of Trustees to appoint a committee to study and report on recommended standards for the operation of such services. Both resolutions had emphasized the valuable public service aspects of grievance committees and had suggested that the committee appointed by the Board of Trustees be composed of representatives from constituent societies in which grievance committees have been effective and useful.

Hospital Accreditation

In place of an Indiana resolution protesting certain situations arising in connection with hospital inspections, the House adopted the following substitute resolution to resolve the problems in question:

"Resolved, that the Secretary of the American Medical Association be directed to request that the Joint Commission on the Accreditation of Hospitals supply a copy of the letter of notification regarding the results of the survey of each hospital to the Hospital Administrator, to the Chief of the Professional Staff and to the Chairman of the Governing Board of the hospital."

Osteopathy

The House concurred in the following supplementary report of the Board of Trustees on the osteopathic situation:

"Contingent on the receipt of the report from the Committee to Study the Relations Between Osteopathy and Medicine of its 'on campus' observations of osteopathic schools, the House of Delegates in June, 1954, agreed to hold in abeyance any action on this important subject until this meeting.

"The Committee, after meetings and extensive negotiations with the American Osteopathic Association, has now made final arrangements for visiting five of the six schools of osteopathy, and these plans have been approved by the Board of Trustees.

"It is the recommendation of the Board, therefore, that consideration of this matter be held in abeyance by the House of Delegates until the June, 1955, meeting, at which time the Committee expects to have a complete report of its findings concerning the nature, scope and quality of education in schools of osteopathy."

The Doctor Draft Law

The Reference Committee on Medical Military Affairs considered several reports and resolutions involving the doctor draft law, and then proposed the following policy statement which was adopted by the House of Delegates:

"(A) That on the basis of current information the House of Delegates commend and express itself as being in complete accord with the Board of Trustees and its Council on National Defense that the 'Doctor Draft Law' should not be extended after June 30, 1955, and that the House of Delegates further express its confidence in the ability of the Board of Trustees and its Council on National Defense to properly handle any new situation which may develop in regard to this highly complex and involved problem.

"(B) That the Board of Trustees and its Council on National Defense continue to study the problem of providing the best possible medical service for members of the armed forces and that they make recommendations to the Department of Defense at the earliest possible time for a more permanent solution to the problem, giving special attention to the further development of a career medical corps with adequate compensation therefor."

State-Subsidized Medicine

Most controversial issue at the Miami meeting was a resolution on "Policy on Medical Practice by Tax Supported Medical Schools," introduced by the Mississippi State Medical Association. This resolution provided that:

> "The American Medical Association reaffirm its unalterable opposition to socialized and state subsidized medicine regardless of the form which it may assume, and
>
> "The House of Delegates of the American Medical Association is of the opinion that these principles should be considered by constituent and component medical societies together with all other facts pertinent to the local situation in all controversies arising in the employment of medical faculty by state (tax) supported medical schools and be fully considered in effecting action within the framework of this policy."

The Reference Committee on Medical Education and Hospitals agreed with that portion of the resolution regarding "unalterable opposition to socialized medicine" but recommended that the resolution be referred, without approval or disapproval at this time, to the Council on Medical Service which currently is studying the various aspects of this subject. The House adopted the reference committee's recommendation.

Eisenhower Reinsurance Plan

Time is not running out for those who believe in the voluntary way toward insurance protection, Edwin J. Faulkner, president of the Woodmen Accident and Life Company of Lincoln, Nebraska, told the delegates. Public opinion surveys show a substantial decline in the number of people who favor compulsory health insurance, he said.

Mr Faulkner also pointed out that a federal reinsurance program will not help private companies to sell unwilling buyers. Nor will it make insurance any cheaper or more easily available to persons or areas which cannot now be reached by voluntary insurance companies. What it will do, in his opinion, is this:

1. To the extent that it encourages extending health insurance to insurable risks, it will result in excessive losses leading to pressure for direct federal subsidies.

2. It will involve a very broad delegation of powers which some later administration might abuse.

3. Participating insurance companies will be subject to government regulation of premium rates on reinsured business. Because of the rapidly changing pattern of health care costs insurers need a maximum flexibility to keep abreast of developments.

Malpractice Insurance

Two resolutions and a Board of Trustees supplementary report—all dealing with the problems and difficulties in obtaining satisfactory professional liability insurance—were considered together by the Reference Committee on Insurance and Medical Service. The House of Delegates accepted the reference committee report which said: "Inasmuch as the Board of Trustees has reported that there is in progress a study on the subject, we feel that we can well await the recommendations that the Board is planning to make at the next session. Due to the apparent emergency aspect of the problem, the Board of Trustees is urged to report to the membership as soon as possible, through its component societies, on the progress of this urgent study."

Opening Session

Walter B. Martin, M.D., AMA President, declared at the opening session that "medicine belongs to the people" and physicians are "merely the purveyors" of medical care. Dr. Martin stressed that physicians have an obligation to the people that "goes beyond our own private practice and into the community," and he also emphasized the importance of "continued effort to meet the medical needs of the low-income and other non-insurable groups."

Mr. Collins, the American Legion National Commander, said that "we are citizens first and doctors and veterans second," as he urged removal of the veterans' medical care issue "from the area of name-calling and propaganda." The American Legion, he declared, neither expects nor wants the Government to give carte blanche entitlement to medical care to all veterans.

Mrs. Hobby, presenting the case for the Eisenhower Administration's health reinsurance proposal, said: "The health reinsurance proposal represents what we believe to be a necessity. It offers opportunity for self-help without subsidy." Mr. Faulkner, however, expressed the opinion that the reinsurance program, "would be foredoomed to disappoint its proponents," and he declared that voluntary health insurance can bring satisfactory protection "to practically all of our people" without a Federal reinsurance program.

Awards and Contributions

At the closing session of the House of Delegates the American Medical Association received a citation for pioneering in helping to bring educational television to the American public. James Keller, chairman of the Miami Citizens Committee for Educational Television, presented the award on behalf of the National Citizens Committee for Educational Television. Dr. Martin accepted the citation for the AMA.

At the same session the Utah State Medical Society, represented by George M. Fister, M.D., of Ogden, presented a check for $10,355 to the American Medical Education Foundation to aid in relieving the financial plight of the nation's

History of Medicine in Minnesota

THE PIONEER DOCTORS OF CHIPPEWA COUNTY PRIOR TO THE YEAR 1900

LEON G. SMITH, M.D.

Montevideo, Minnesota

(Continued from October, 1954, issue)

It was upon Frink's farm, homesteaded in 1867, that much of Montevideo was built. What finally determined the future of the two villages, Chippewa City and Montevideo, was the location of the post-office, and that was brought to Montevideo by the superior foresight of its citizens. The mail was brought up the old Military Trail on the south bank of the Minnesota; and, since Montevideo was the first to build a ferry across the Minnesota below the mouth of the Chippewa, the mail was then brought up along the east bank of the Chippewa, with the natural result that they moved the post-office to the Montevideo side rather than transport the mail further across the river to Chippewa City.

The village was platted in 1870, the year in which the post-office, a schoolhouse and a hotel were built. The sawed lumber for the post-office was hauled 100 miles, but the roof was made from bark, stripped from elm trees and then covered with dirt. The floor was of dirt, with a thick carpet of hay, necessitating rather high stepping. Counters in stores consisted of posts driven into the ground with boards laid across. On February 28, the same year, Montevideo was designated the county seat by action of the Territorial Legislature, and this spelled "finis" to Chippewa City.

Only two years later we come across the name of Montevideo's first physician, Dr. Murphy.

Dr. Lea Murphy was born in Wisconsin, November 27, 1849. His family consisted of his parents, three brothers and nine sisters. When he was seven years old, the family moved to St. Charles, Minnesota, where he attended public school and became interested in medicine, reading the medical books of his Grandfather Sedduth. He entered Rush Medical College in Chicago in 1871. On October 8 to 9 of that year the famous Chicago fire occurred, and he had to walk for miles hauling a little cart, on which was his trunk, containing his books and other student equipment.

In the summer of 1872, he drove to Montevideo by horse and sulky with what little medical equipment he owned, a pair of saddle-bags, and twenty-five dollars in cash. At that time, his nearest competitor was located at Redwood Falls, and his territory extended from Benson to the Dakota line, west of Canby. Two years later, Dr. Stratton located at Granite Falls.

Requirements for medical practice were not at all rigid at the time, and he was able to practice without a license. In fact, he was probably better equipped for his work, by his year in medical school, than many other doctors who had located in the new country. Many of them had picked up the rudiments of medicine and surgery, working as surgeon's aids, or hospital attendants during the Civil War, and then had simply set themselves up as physicians and surgeons.

Apparently his practice was a lucrative one, because within a year he had made enough money to return to medical school and complete his studies, graduating from Rush Medical College in 1874, and returning to Montevideo.

In 1875 he was married to Ruth Helen Lawrence, and three children were born to this marriage: son, Lloyd L., in 1876; daughter, Nelbert, in 1878; and, son, Lea M., in 1885.

A law passed in 1883, required practitioners of medicine to obtain a license. It exempted those who had practiced in the state for five years. (Four years later in 1887, the legislature passed a more stringent law, repealing the law of 1883 and prohibiting anyone from practicing medicine without a license under penalty of fine, or imprisonment, or both).

Evidently, Dr. Murphy practiced for nine years without one, none being required or, presumably, even obtainable. But October 11, 1883, he obtained his license, Number 45, making him one of the earliest licensees in the state.

In 1878, he developed a very severe case of rheumatic fever which incapacitated him for many months. Probably, as the result of this illness, and the necessity for avoiding some of the more strenuous duties of medical practice, he entered the drug business with O. A. Griffis. His brother, Will, who worked as a clerk in the drug store for several years, eventually bought out Mr. Griffis, bringing the drug store under the ownership of the two Murphys, and under the name of the Murphy Drug Store, it continued in active business until 1921.

Old files of the *Montevideo Leader* (December 9, 1882) record his performance of a difficult operation upon J. J. Skonard, working with Dr. Rogers. "After the patient was chloroformed, an extensive canal was found, leading from an opening on the left side of the neck as far as the angle of the jaw. The dissection was made in the region of important blood vessels and nerves, which had to be carefully avoided, as a little slip might have proved a very serious matter. Three hours of skillful manipulation brought out the sac entire, known among surgeons as a dermoid cyst. We understand the young man is doing well and the doctors think he will have no further trouble." December 31, 1886, mention was made of a new phone connecting his house and office, which must have been one of the first instruments in the county. On May 13, 1887, there was an account of his performing a difficult operation, assisted by Drs. Rogers and Moyer, upon Magnus Quamen of Milan, wherein "a large, fistulous tract, draining a necrotic area of the coracoid, as well as the acromion, process of the scapula, leading across the brachial plexus, and discharging upon the skin of the upper arm, was opened, the necrotic bone chiselled out, and the wound dressed. At present account the patient is doing well."

He spent the winter of 1889 on the Pacific Coast, and in 1890, he "packed his household goods and shipped them to Minneapolis, where he moved with his family, and assumed his new duties as Medical Examiner and Manager of the Mount Benevolent Insurance Association. The community regrets their leaving after almost twenty years among us."

March 16, 1894, he was in Montevideo forming the Globe Fraternal Accident Association, which insured the I.O.O.F. (Independent Order of Odd Fellows) only.

He must have shuttled back and forth between Minneapolis and Montevideo two or three times in the next few years, because the *Montevideo Advance* of

June 5, 1896, announced that "Dr. Murphy's goods and family have arrived, and they are looking for a place in which to live."

Shortly thereafter, he bought a sanatorium, for tuberculosis and other respiratory diseases, in Minneapolis. The *Montevideo Commercial* of November 19, 1897, has an article as follows: "There was a bad fire in Dr. Murphy's Sanatorium a few days ago, caused by a burning nebulizer. Dr. Murphy, in his heroic efforts to prevent the fire's spread, and in throwing the nebulizer out of doors, sustained severe burns of the hands and arms. Twenty-two patients were moved to Dr. Rogers' Sanatorium." (Dr. Rogers was a former confrere of Dr. Murphy in Montevideo, and at the time, was running a similar institution in St. Paul.)

In 1899, he had again returned to Montevideo and, in 1900, he took several months of post-graduate work at Rush Medical College, following which, he moved his family to Badger, Roseau County, Minnesota, practicing medicine and conducting a drug-store there for a few years. He moved back to Montevideo in 1906, and again assumed an interest with his brother in the Murphy Drug Store, which he retained until 1919.

It was during this period that I became acquainted with him. He was a delightful man to know, full of wit and humor, and with a gift for anecdote. I greatly enjoyed his stories of his pioneer days. The one that especially impressed upon me the arduous work he had formerly done concerned a prolonged typhoid epidemic one fall. He had so many cases, extending all the way to Benson (over thirty miles), that it would take him all of a day, driving across the prairies and around the sloughs to visit half of them. After spending the night in Benson, the next day, on his return trip, he would visit the remainder. Far into the night he did his work in Montevideo, starting out again the following morning upon a repetition of his two day trip. This epidemic lasted for several weeks. Small wonder he was ready to turn to the less strenuous work of running a drug store.

He moved to Pasadena, California, in 1919 and died there in 1923. His older son, Lloyd, and his daughter, Nelbert Murphy Chouinard, still live in the Los Angeles area.

I have attempted to assemble the biographical sketches of the doctors, who succeeded Dr. Murphy, as nearly as possible in the chronological order in which they located in the county. There were apparently several who settled here for a short time in the 1870's and early 1880's, but information concerning them is meager.

Probably the first to locate after Dr. Murphy, was **Dr. Charles E. Daniels.**

In the *Montevideo Commercial* of August 7, 1887 there appeared, copied from the *Milbank Review,* a story concerning Dr. Daniels, at that time located in Milbank, South Dakota: "Dr. Daniels was born about 1840, and while still only a boy, enlisted in the U. S. Army, February 17, 1865. He was in Company D of Bracketts' Indian Battalion, serving under General Sully. During the winter of 1865-66, he acted as scout, chasing Indians, trapping beaver and hunting buffalo all through the region extending from what is now Sioux Falls to Milbank. After his discharge in May, 1866, he returned to Hastings, Minnesota, to finish school, and then went on to college at Hamline University in St. Paul and at Bennett Medical College in Chicago. After graduating from the latter, he located in Goodhue County in 1876, moved to Montevideo, Minnesota in 1878, and to Milbank, South Dakota in 1881." (A professional card in the *Montevideo Leader* of January 14, 1882, but gone by the issue of July 1, 1882, would indicate he moved from Montevideo to Milbank during early 1882.) "He is now 40 years old, is president of the Milbank Board of Health, and has enjoyed a lucrative practice for several years."

Evidently Dr. Daniels lived and practiced in Milbank the remainder of his life.

Another doctor who practiced in Montevideo for a short time during this period was **Dr. George E. Dennis.** He was born in Livonia, Michigan, November 27, 1839, and grew up there. He served in the First Michigan Cavalry during the Civil War. In 1868, he moved to Hastings, Minnesota, where he engaged in farming until 1879. He had begun the study of Medicine at home and later worked under the preceptorship of Dr. Hawes of Hastings.

There is no record of any acquaintanceship between him and Dr. Daniels, but both living in a small town the size of Hastings, it is reasonable to assume they were friends and that, when Dr. Daniels decided to leave Montevideo, he induced Dr. Dennis to come here and take his place. At any rate, Dr. Dennis came to Montevideo in 1880 and practiced here until he made enough money to complete his medical education as a homeopathic physician, graduating from Hahnemann Medical College of Chicago in 1883.

His Minnesota license, number 44, dated October 11, 1883, was a very early one.

The *Montevideo Leader* of October, 1882, stated: "Dr. G. E. Dennis leaves for the winter at Hahnemann Medical College, expecting to return in the spring. He has been here for two and a half years and has built up a fine practice, and we regret his temporary absence."

After graduation, he returned to Montevideo, but for only a short time, as he moved to Minneapolis in 1884 and practiced there until his death May 22, 1907. He was one of the better known doctors of Minneapolis during that time, and there are several biographical sketches of him. The best is in a "History of the First Presbyterian Church of Minneapolis," by A. B. Marshall.

Dr. Joseph B. Bacon located in Montevideo at the same time as Drs. Murphy, Daniels and Dennis. He remained for a somewhat longer period, but is not to be confused with **Dr. R. S. Bacon,** who came to the village about the time Dr. J. B. Bacon left, staying here for many years.

Dr. J. B. Bacon was born in Illinois in 1854. He attended Northwestern College of Chicago until 1876, Chicago Medical College until 1878, and the next year graduated from Texas Medical College. He practiced one year at Elliott, Illinois, and was then appointed assistant physician in the Cook County Hospital. Apparently, he did more medical studying during that time, as he is again listed as graduating from Chicago Medical College in 1881. He did not obtain his Minnesota license until December 21, 1883, so he, also, was one of those doctors who practiced without a license prior to the License Law of that year.

He was mentioned in several news items of the Montevideo papers up to the late 1880's. The *Montevideo Commercial* of May 9, 1892, had the following item: "Dr. J. B. Bacon, once a practicing physician here, is now a resident of Chicago. He has associated himself with several other physicians to start a medical school and hospital. Instead of lectures and a dissecting room, students will be given actual work upon patients under competent direction. All demonstrative work will be done at the bedside and classes will consist of but six students."

Dr. Bacon was listed in Polk's Medical Directory as being in Chicago in 1895 and 1898, but in 1903, he was listed from Macomb, Illinois, his name reappearing from there in each issue until 1927. The American Medical Association recorded his death July 21, 1936, with place of residence or death not given.

The listing of the "Causes of Death" for Chippewa County for the year 1881 makes interesting reading, by comparison with the present, with eighteen deaths under one year of age, ten between the ages of one and five, and only six over the age of sixty. This forcefully points up the change that has taken place in our mortality statistics as our country has grown older, showing an extremely high rate among infants and young children and a very low rate among older people in this report.

Causes of Death	*Number of Cases*
Diphtheria	13
Consumption	6
Typhoid fever	4
Cholera infantum	2
General debility	2
Spasms	2
Heart disease	2
Accidents	2
Various diseases	10
Not known	15

Accidents seem to have occurred at this time as frequently as at present. Accounts of injuries sustained by run-away horses, or of farmers being gored by bulls appeared in place of our present-day automobile smash-ups or corn-picker tragedies. And, of course, such terms as "black smallpox," "black diptheria," "typhlitis," "membranous croup" and "pest-house" sound strange to us now.

Dr. Ottul Klaranus Lindboe was located in Chippewa County for only a short time, but he was such an interesting person and he lived for so many years near the village of Lac qui Parle, that he was close enough for Montevideo to claim him as a member of our community. He was born November 16, 1851, in Konsberg, Norway, the son of Andere and Else Lindboe. He there lived until after his confirmation, when he moved to Christiania and worked by day and attended school at night.

After his father's death, his mother, who was a doctor, came with him and his brother to America in April, 1867. The trip took eight weeks and whatever food they needed on the journey they had to prepare themselves. They landed in Quebec and traveled from there to Sarnia, Ontario, overland by ox-cart. Crossing into the United States at Detroit, they took a boat to Chicago, where he worked as a painter during the day, attending night school long enough to learn to speak English.

In July, 1867, he set out with his uncle for the gold fields of Colorado, where he stayed a year and was fortunate enough to pan out about $5,000. On his return trip, however, he was not so fortunate, because, carrying his money and belongings in a knapsack and sleeping out doors, he awoke one morning to find himself robbed. Reaching Chicago penniless, he found his mother and brother Andrew had bought a drugstore. There he worked, and did painting and helped clean up the debris after the Chicago fire. He wanted enough money to secure an education, so he joined a party and set out upon a second trip to the gold fields. Again misfortune struck. The party was attacked by Indians for nine days and they finally had nothing to eat but raw mule meat. Lindboe was wounded, and for the rest of his life carried the scars of an Indian arrow in his leg and a bullet in his side.

Upon his return to Chicago, he studied pharmacy, and graduated in 1873. But he at once went on to study medicine at Northwestern University for one year, then at Rush Medical College, graduating in 1877. His brother, Andrew, graduated from the same school shortly thereafter, and the two started practice together, but Andrew soon contracted tuberculosis and died. After that, Ottul and his mother practiced a short time in Ironwood, Michigan. He came to Minnesota, practicing a short time in the vicinity of Red Wing and Cannon Falls, and, in 1879, was married to Anna Christina Johnson, of Beloit, Wisconsin.

The following year, he and his bride came to Montevideo, but remained only a short time before moving to Lac qui Parle Village, which, at that time, was one of the largest settlements in western Minnesota and reputed to have a population of over nine hundred.

During the winter of 1881, known as the "year of the big snow," Dr. Lindboe had to make his professional calls on snow shoes and skis, the snow being four feet deep on level ground. In later years, Dr. Lindboe liked to reminisce about that first winter, when people lived in sod houses with snow piled so high over them, that the only sign of life was smoke rising from the chimneys, which barely protruded above the drifts. Tunnels were dug between house and barn; slanting shafts were dug down to the house door in order to get in and out; and holes were cut in the barn roof to enter and care for the stock. On several occasions he came home from his calls with frost-nipped hands or feet or face.

After some years of practice with his office in Lac qui Parle Village, Dr. Lindboe began to suffer a great deal from rheumatism. Because of this he bought a farm a short distance north of the village. This he worked as a farmer, but he also administered to the medical needs of his neighbors for many years, and, in the absence of a dentist in the area, extracted many aching teeth. It is interesting to mention that he brought the late Governor Theodore Christianson into the world.

During his life in the community, he served for thirty years on the school board, and many terms on the township and health boards. He was for many years a member of the board of directors of the four-county Riverside Tuberculosis Sanatorium located near Granite Falls.

He was taken sick in January of 1942 and after a three weeks illness passed away February 7, 1942, at the age of ninety.

Dr. and Mrs. Lindboe had five children: one son, Andrew; and, four daughters, Ella (Lund), Clara (Anthony) and twins Elsie and Laura (Dahl). Mrs. Lindboe and Ella had preceded him in death, but his remaining four children, with many grandchildren and great-grandchildren, are living, many of them still in the Lac qui Parle area.

Prior to the year 1881, the only doctors who had located in Chippewa County had settled in Montevideo, but in that year **Dr. Nels Amherst Nelson** began practice in the village of Watson.

Dr. Nelson's parents were born in Norway: his father, Nels Bakken in Narvik, and his mother in Christiania. Nels was born in Lake Mills, Iowa, in 1858, one of a family of six children. He attended elementary school at Lake Mills and college at a small institution in Wisconsin, which was probably Ripon College. His medical education was obtained under the Eclectic School of Medicine in Eclectic Colleges in St. Louis, Missouri, and in Minneapolis, Minnesota. He also attended a post-graduate course at Rush Medical College in Chicago, Illinois, and graduated in 1880.

He moved to Watson, Minnesota, and during the next two years practiced in Chippewa County at Watson and Milan. Later he located in Appleton, Minnesota.

In 1880, he was married to Jennie Boe, a girl who lived a few miles east of Milan. She was born in Lier, Norway, in 1858, and had moved to this country with her parents when she was thirteen years of age, and was living near Milan when she met Dr. Nelson. Two children, a son and daughter, were born to their marriage.

Polk's Medical Directory states that Dr. Nelson graduated from the Eclectic Medical College of Des Moines, Iowa, in 1884, but this may be an error, because the *Montevideo Leader,* of September 16, 1882, recorded, "Dr. Nelson was called from Appleton to perform the amputation of an arm. He was assisted by Dr. J. B. Bacon and Nels Bergstrom." There is, of course, the possibility that, like many another physician of his day, he practiced at intervals, interspersed with periods of study in medical school. In any event, graduate or not at the time, he must have attained a considerable degree of skill to be able to do an amputation.

He received his Minnesota license June 25, 1885, and, at about that time, moved from Appleton to Dawson, Minnesota, where he practiced until his death in August, 1929.

He was one of the earliest settlers in that village, moving there at the time the Minneapolis and St. Louis Railroad was extended through Dawson. His residence was the third house built in the town.

For most of his life, he practiced alone. He was a life-long member of the Lutheran Church, and for many years a member of the Masonic Lodge. He also was a charter member of the Camp Release District Medical Society, and attended its meetings regularly and did a great deal of community welfare work. For many years he was village Health Officer. He had a wonderful bedside manner with his patients.

His outside interests were in hunting and fishing, and he was especially fond of violin music, of playing the violin himself, and of singing.

One sister and two brothers survive him, as well as his son and daughter. His son, Dr. Melvin S. Nelson, has been practicing medicine in Granite Falls, Minnesota most of his professional life, and is one of the oldest and best known doctors in western Minnesota.

Dr. Hans J. G. Koren is another physician who appears to have been practicing in Montevideo at the time of his licensure, December 28, 1883. He was born in Norway, and received his medical education at King Frederick University, graduating in 1869. He must have practiced in Norway for several years, because his son, Finn, later to become a Chippewa County doctor, was listed as having been born in Norway in 1873. Some time between 1873 and 1883, Dr. Koren moved his family to this country and settled in Montevideo, where he practiced, probably until Finn graduated from Windom Institute in the class of 1891. He and Mrs. Koren must then have returned to Norway for several years, because in the *Montevideo Commercial* of November 12, 1897, we find this item: "Dr. and Mrs. H. J. Koren, formerly of this village, who have been living in Norway for several years, are returning to the U. S. They will locate in Lamberton, Minnesota."

The *Montevideo Leader* of November 3, 1899, had the following: "Dr. H. J. Koren, formerly of this village, but later of Lamberton, died October 31, 1899, at St. Barnabas Hospital, Minneapolis, Minnesota, of appendicitis and resulting peritonitis, after six days' sickness. Pallbearers will be classmates from the University of Norway. Mrs. Koren will reside with her son, Finn, who is studying medicine at the University of Minnesota."

We next come to one of the most interesting personalities we will encounter in the history of the county, **Dr. Charles E. Rogers.** All the evidence seems to indicate that he was a man of strong convictions, boundless ambition and unlimited energy. There were no half-way measures with him. People were either his very good friends or his enemies. He lived and practiced off and on in Montevideo for thirty years, and during that time, exerted a powerful influence upon the community.

Charles Emory Rogers was born in Jefferson, Ohio, October 1, 1850, the son of Henry and Melinda Hoyt Rogers. Both of his parents were born in New York. When a lad, his family moved to Mauston, Wisconsin, where he obtained his elementary schooling. He followed this, by attending business college, teaching country school for a while, and later becoming part owner and teacher in a business college in La Crosse, Wisconsin. He was married to Rose Turner, of Mauston, at Wisconsin Dells in 1870.

He remained at La Crosse several years, and during that interval took up the study of medicine under the tutelage of Dr. Knut Hoegh, at that time, one of the best known surgeons west of Chicago. This was followed by a regular course of medical study at the Bellevue Hospital Medical College in New York City. After graduating in 1880, he returned to La Crosse and became associated with Dr. Hoegh. During this time, he was made a surgeon in the Third Regiment of the Wisconsin National Guard, with the rank of major.

An old boyhood friend from Mauston, H. E. Hoard, in the meantime, had settled in Montevideo, and had bought the *Montevideo Leader,* of which he was manager and editor. Later he was elected to several terms in the State Legislature.

Undoubtedly, as the result of this friendship, Dr. Rogers was induced to locate in Montevideo, which he did in the late fall of 1882.

Almost immediately he became a leader in the community. He was appointed surgeon of the C. M. and St. Paul (Milwaukee) Railroad, in which capacity he served until his death. He was a member of the State Medical Board for many years and for a number of years, was a teacher of anatomy, physiology and hygiene in Windom Institute. At various times he was a member of the village council and a director of the Citizen's State Bank.

(To be continued)

THE DEAN'S PAGE

medical practice. The return of the Medical Library to the Medical Campus will make this possible. We most earnestly hope, therefore, that the 1955 Legislature will make the appropriation requested for this purpose.

Additional funds for remodelling and equipment of the University Hospitals and Mayo Memorial are needed because large areas, such as the operating rooms, x-ray department, clinical and research laboratories and departmental and administrative offices were removed from the hospital into the new building. The areas thus vacated need to be remodelled into rooms and wards for patient care. In addition, much of the plumbing and electrical work in this old building needs replacement, and considerable areas of the Outpatient Clinic need reconditioning and modernization.

The medical faculty will appreciate any assistance in the support of these appropriations which the physicians of the state are able to give.

Harold S. Diehl

In Memoriam

WILLIAM H. GOECKERMAN

Dr. William Goeckerman, member of the Mayo Clinic staff from 1921 to 1932, died November 8, 1954, in Los Angeles. He was seventy years old.

Dr. Goeckerman was born in Hanover, Germany, and received his medical degree from the Wisconsin College of Physicians and Surgeons in Milwaukee. He entered the Mayo Clinic as an assistant in dermatology and syphilology in 1917 and became an associate in 1921. He was also associate professor of dermatology in the Mayo Foundation. He practiced in Los Angeles upon leaving Rochester and was consultant at St. Vincent's Hospital and the California Hospital and clinical professor of medicine at the University of Southern California.

During his stay in Minnesota, Dr. Goeckerman was a member of his county medical society and of the Minnesota State Medical Association and the American Medical Association. He was also a member of the American Dermatological Association and many other scientific associations.

Surviving are his wife, the former Magdelana S. Moore, and several brothers.

JOHN FRANCIS NORMAN

Dr. J. F. Norman, of Crookston, died at the age of seventy-four in his home at Crookston on November 29, 1954. Dr. Norman was founder of the Crookston Clinic and was still actively associated with it. He died suddenly after a cerebral hemorrhage which occurred while he was putting on his overshoes to return to the clinic at noon.

Dr. Norman had been a leader in medical affairs in Minnesota for many years. He served as president of the Minnesota State Medical Association in 1951 and had been elected to all of the offices that his local and district medical organizations could bestow.

He was a member of the board which established the Blue Shield program in Minnesota and was a member of the American Medical Association as well as his local Red River Valley Medical Society and the state association. He was also a long-time member of the American College of Surgeons and a member of Rotary.

Born in Henderson, Dr. Norman taught school for five years in order to earn funds to go to college. He was graduated from Hamline University Medical School shortly before the school became part of the University of Minnesota Medical School in 1905. He served his internship at St. John's Hospital in Fargo, North Dakota, and later did some postgraduate work in Europe.

He is survived by his wife, the former Loretta Malone; two sons, Dr. David D. Norman, 1883 Goodrich Avenue, St. Paul, and Nelson F. Norman, Ph.D., Fresno State College, California; a daughter, Mrs. H. R. Perry, Santa Fe, New Mexico; a sister, Mrs. Mae Working; and seven grandchildren.

WILLIAM HENRY ROWE

Dr. William H. Rowe, seventy, died December 2, 1954, in Fairmont where he had practiced eye, ear, nose and throat work since 1935.

Dr. Rowe was the son of a physician who practiced in St. James, where he was born in 1884. He went to school in St. James and obtained a bachelor of arts degree at the University of Minnesota and a medical degree from Rush Medical College of Chicago in 1909. He served his internship at St. Mark's Hospital in Salt Lake City and took a year of post-graduate work at Knapp Memorial Hospital and Roosevelt Hospital in New York City. He practiced at St. James from 1910 to 1922 and in Minneapolis from 1922 to 1934.

In 1935 Dr. Rowe moved to Fairmont and remained there until his death.

AMERICAN MEDICAL ASSOCIATION

Proceedings of House of Delegates

(Continued from Page 58)

medical schools. The contribution was received by Louis H. Bauer, M.D., president of the foundation, who also announced that a check for $1,000 had been contributed by the Southern Medical Association.

1957 Clinical Meeting

Philadelphia was chosen as the place for the 1957 Clinical Meeting, the dates of which will be announced later. Invitations also had been received from Denver, Detroit, Mexico City and Washington, D. C. The Clinical Meeting will be held in Boston in 1955 and in Seattle in 1956.

Health Fair

As the AMA Clinical Meeting came to a close on Thursday, December 2, a health fair for the public opened in Miami's Bayfront Auditorium under the auspices of the Dade County Medical Society. The fair, to be open through Sunday with more than eighty exhibits featured, marks the first time that such an event has been held in connection with the AMA Clinical Meeting.

Woman's Auxiliary

WORKING TOGETHER FOR HEALTH AND SAFETY

MRS. DAVID J. HALPERN
Brewster, Minnesota

First, I would like to congratulate Martin county for its splendid hospital auxiliary. You are the group who volunteer your services to the hospital. You are the ones on whom the administrator can call to raise funds for your hospital. You—who are well informed about the needs and facilities of your hospital—can go out among your friends and organizations and give them the correct information and thus create good will toward your hospital and an appreciation of the hospital as a community enterprise. Through education, information and service you are working for better hospital care for the people of your community. The greatest gift an individual can give to her community is a "little bit of herself."

The purpose of the medical auxiliary is health education and service. Hence, it seems very fitting that these two groups should have a joint meeting.

The United States has the world's highest standards of health and medical care. It is the world center of medical education and research. This has been accomplished by physicians with the co-operation and help of allied professions, branches of science, nurses, hospitals, etc. In fact, through the help of many branches of American society.

We know that many dread diseases that once were killers (typhoid, diphtheria, small pox, pneumonia and many others) have been brought under control. Yet, we do very little about the *unnecessary* deaths—those killed by accidents. Just this last weekend there were fourteen highway deaths in our own state of Minnesota. There were 38,000 highway deaths in our nation last year. This is more than the number killed in the Korean war. I haven't the figures, but if we were to add to those the number killed in farm, home and industry accidents, I am sure the number would be startling.

Think, too, of the millions who are injured—to say nothing of the economic loss. It makes us realize that safety, as a health measure, should be stressed. It is only a short step from carelessness to danger. The medical auxiliary is placing its accent on home and playground accidents. There is a definite place for each of you in this community action. Saving *healthy* lives is as important as saving *diseased* ones.

All of us are interested in well-trained personnel for our hospitals. You might interest the young people in your own family in the nursing profession. The shortage includes, besides registered nurses, practical nurses, medical record librarians, x-ray and laboratory technicians, dietitians, physical and occupational therapists, health educators, etc. Boys, as well as girls, should play an important part in filling these positions. You might interest high school students in these professions through teas, a panel discussion made up of nurses and those in the allied professions. You might tour your local hospital. You might see that nursing and allied professions are included if you have high school career days. You might sponsor essay or poster contests.

Another field in which we should all co-operate and work together on is civil defense. Our Auxiliary bulletin says: "Effective mass public education is the key to national survival—if war should come, women know that "a stitch in time saves nine." Are we, as women, delaying in taking the needed stitch? Many skilled and willing hands are needed. Points we are asked to stress are these:

"1. Home protection exercises. Every woman's first duty in the civil defense program is to educate her family in self protection against modern weapons and to make her home as safe as possible against both the dangers of enemy attack and disasters such as fire, flood, tornado.

"2. Home nursing classes.

"3. Education in the areas of sanitation, mass feeding, and temporary housing.

"4. Co-operation with the medical profession in preparedness."

We can each continue to render our valuable assistance to the Red Cross blood program. As you know, this program not only provides gamma globulin for polio, measles and hepatitis, but also furnishes free blood to our hospitals for community use.

The American Cancer Society, Heart association and other such agencies deserve the support of all Americans.

You can volunteer your services for the various types of testing in schools such as Mantoux test for immunization programs. You can help at the clinics for crippled children, at diabetic surveys.

These are a few of the fields in which you can help as volunteers. Someone said, "It is hard to imagine American life *minus its volunteers.* Let's hope they never go on 'strike'."

We, who are members of the Hospital Auxiliary and the Medical Auxiliary, should all *work* together for the health and safety of our community. I would like to close with an expression from India: "He who would leave footprints in the sands of time must wear *work* shoes."

(Continued on Page 71)

Presented at a combined meeting of the Martin County Hospital Auxiliary and the Auxiliary of the Minnesota State Medical Association, Fairmont, Minnesota, October 13, 1954.

Mrs. Halpern is recording secretary, Woman's Auxiliary to the Minnesota State Medical Association.

Reports and Announcements

MEDICAL MEETINGS

State

MINNESOTA STATE MEDICAL ASSOCIATION, annual meeting, Minneapolis, May 23-25, 1955.

National

American Cancer Society, Board of Directors and special committee meetings, Hotel Radisson, Minneapolis, June 2, 1955.

American College of Surgeons, sectional meeting, The Fort Harry, Winnipeg, Manitoba, Canada, April 25-26, 1955.

American Medical Association, annual meeting, Atlantic City, New Jersey, June 6-10, 1955.

Conference on Reserpine in the treatment of neuropsychiatric, neurological and related clinical problems. Barbizon-Plaza Hotel, New York City, February 3-4, 1955.

International

International College of Surgeons, United States Section, Southwestern Division regional meeting, Shamrock Hotel, Houston, February 28-March 1, 1955.

Inter-American Congress of Radiology, Shoreham Hotel, Washington, D. C., April 24-29, 1955.

International Hospital Congress, Lucerne, Switzerland, May 30-June 3, 1955.

International Symposium on Cardiovascular Surgery, Henry Ford Hospital, Detroit, March 17-19, 1955.

AMERICAN ACADEMY OF FORENSIC SCIENCES

The Seventh Annual Meeting of the American Academy of Forensic Sciences will be held in the Biltmore Hotel in Los Angeles on February 17-19, 1955. The president of the Academy this year is Dr. A. W. Freireich, Malverne, New York, and the chairman of the Program Committee is Dr. Milton Helpern, Chief Medical Examiner of New York City. The law department of the American Medical Association has long urged that the profession take an increasing interest in medicolegal problems and the programs of the Academy meetings are a definite step in that direction. Further information may be obtained by writing Dr. W. J. R. Camp, University of Illinois College of Medicine, 1853 W. Polk Street, Chicago, Illinois, secretary, or Dr. Frederick D. Newbarr, 109 Hall of Justice, Los Angeles 12, California, chairman of local committee on arrangements.

FAMILY DOCTORS' DAYS
at the
University of Minnesota Hospitals

All physicians are cordially invited to attend the following Family Doctors' Days which will be presented under the direction of the department indicated.

January 19—Hospital Administration
February 16—Division of Anesthesiology
March 16—Division of Urology
April 20—Division of Neurosurgery

Activities begin with luncheon at 12:15 noon with the staff of the Department in the Hospital Dining Room and will continue throughout the afternoon.

For further information, write the head of the department concerned or the Director, Department of Continuation Medical Education, University of Minnesota Hospitals.

AMA COUNCIL ON EDUCATION AND HOSPITALS

The Council on Medical Education and Hospitals of the AMA is planning a program on the subject of "The Potential Use of Television in Postgraduate Medical Education" to be presented as a full-day working conference on February 5, 1955, in the ballroom of the Palmer House, Chicago. This is expected to be the first of a series of annual "workshop" type conferences on one particular aspect of postgraduate medical education. Television is the subject of the first meeting because of the extreme interest in this medium that has been shown recently, as well as its pertinence to the future of postgraduate education.

The program is planned in such a way as to present both the educational and technical aspects of the subject, so that medical educators and medical society, hospital and specialty society representatives at the meeting will be able to obtain a broad picture of the medium and help them to determine whether or not it is something they might use in their own programs, and if so the problems involved in its use.

Following a keynote address by Dr. John Cline, the morning session will be devoted to considerations of the purely educational aspects of the medium. The afternoon session will deal with technical considerations and financing. The participants will be drawn from the fields of general education, television, industry, medicine, medical education, pertinent government agencies and others. It is planned to have a number of demonstrations in the afternoon session using actual camera chains and receiving equipment. Following the session it will be possible for the audience to examine these and observe some of them in further action, and visit a local television station in action.

POSTGRADUATE COURSE ON DISEASES OF THE CHEST

The Council on Postgraduate Medical Education of the American College of Chest Physicians, in co-operation with the respective state chapter of the College as well as the staffs and faculties of the local hospitals and medical schools of Philadelphia, will sponsor the Eighth Annual Postgraduate Course on Diseases of the Chest, to be held at the Bellevue-Stratford Hotel, Philadelphia, Pennsylvania, March 7-11, 1955.

Our postgraduate courses endeavor to bring physicians up to date on recent advancements in the diagnosis and treatment of heart and lung disease. Tuition is $75.

Further information may be secured by writing to the Executive Director, American College of Chest Physicians, 112 East Chestnut Street, Chicago 11, Illinois.

ESSAY AWARD CONTEST

The Council on Undergraduate Medical Education of the American College of Chest Physicians offers three cash awards to be given annually for the best contribution, prepared by any undergraduate medical student studying for a degree in medicine, on any phase of the diagnosis and treatment of chest diseases (heart and/or lungs).

The first prize will consist of a cash award of $250. Second prize will be $100 and third prize, $50. The three winners will also receive a certificate of merit.

The winning contributions will be selected by a committee of well-known chest specialists and will be announced at the 21st annual meeting of the American College of Chest Physicians, to be held in Atlantic City, New Jersey, June 2-5, 1955. All manuscripts become the property of the American College of Chest Physicians.

Applicants are requested to study the format of DISEASES OF THE CHEST as to length, form, and arrangement of illustrations to guide them in the preparation of the manuscript. The following conditions must be observed:

1. Five copies of the manuscript typewritten in English (double spaced) should be submitted to the Executive Director, American College of Chest Physicians, 112 East Chestnut Street, Chicago 11, Illinois, U.S.A., not later than April 10, 1955.

2. The only means of identification of the author shall be a motto or other device on the title page and a sealed envelope bearing the same motto on the outside enclosing the name and address of the author.

3. A letter from the Dean or Chairman of the Department of Medicine of the medical school certifying that the author is a medical student studying for his degree in medicine.

LECTURES AND DISCUSSIONS ON CURRENT MEDICAL PROBLEMS

The Mayo Clinic and Mayo Foundation announce a four-day program, April 19 to 22, inclusive, of lectures and discussions on problems of current interest in the general fields of medicine and surgery. The number of physicians and surgeons who can be accommodated is necessarily limited. Those wishing to attend should communicate with Dr. N. W. Barker, Mayo Clinic, Rochester, Minnesota, before March 1, 1955. Applications will be honored in the order in which they are received. There is no registration fee.

MINNESOTA SOCIETY OF NEUROLOGY AND PSYCHIATRY

A regular meeting of the Minnesota Society of Neurology and Psychiatry was held January 11 at the Town and Country Club. Dinner at 6:30 p.m. followed a social hour. During the evening, Dr. James H. Lyons and Dr. Ian A. Brown were voted into the Society as active members. The scientific program included two topics, "Modern Treatment of Brain Abscess" by Harold F. Buchstein, M.D., and "Children's Inpatient Psychiatry Service" by Reynold A. Jensen, M.D.

MINNESOTA TUBERCULOSIS AND HEALTH ASSOCIATION

The changing problem in tuberculosis and new measures of tuberculosis control were the topics discussed by James J. Waring, M.D., professor of medicine, emeritus, University of Colorado, Denver, Colorado, and Howard M. Payne, M.D., professor in medicine, Howard University College of Medicine, Washington, D. C., at the annual meeting of the Minnesota Tuberculosis and Health Association, October 11, 1954.

The meeting emphasized the importance of the Christmas Seal sale, which opened November 22, in supporting an expanded program in the fight against tuberculosis. The officers of the Minnesota Tuberculosis and Health Association who were re-elected are as follows:

President—Ray M. Amberg, Saint Paul
First Vice-President—Montreville J. Brown, Saint Paul
Second Vice-President—Mrs. H. E. Johnson, Stillwater
Secretary—W. H. Valentine, M.D., Tracy
Treasurer—T. C. Macoubrey, Saint Paul
Executive Secretary—E. A. Meyerding, M.D., Saint Paul

CONTINUATION COURSES

The University of Minnesota announces a continuation course in *Clinical Dietetics for Dietitians* which will be held at the Center for Continuation Study next March 3 to 5, 1955. Recent advances in medicine and their relationship to the field of dietetics will be taken up. The course will be presented under the direction of Gertrude Thomas, director of Nutrition and professor of Dietetics, University of Minnesota.

* * *

The University of Minnesota announces a continuation course in *recent advances in internal medicine for internists* which will be presented at the Center for Continuation Study from February 14-16, 1955. This year's course will deal with various aspects of hematology, cardiology, endocrinology, and respiratory physiology. The course will be presented under the direction of Dr. C. J. Watson, professor and director, Department of Medicine.

* * *

A continuation course in *clinical hematology for physicians* will be presented by the University of Minnesota at the Center for Continuation Study from February 28 to March 2, 1955. Registrants will be provided with slides for study during the course showing examples of various blood cell types and of the more frequent hematological diseases. Lectures will include discussions of the anemias, the leukemias, and coagulation defects. Registration will be limited.

RANGE MEDICAL SOCIETY ELECTS

Dr. T. R. Schweiger of Hibbing was elected president of the Range Medical Society when the group met last month in Hibbing. Dr. John S. Siegel of Virginia was named vice president and Dr. Kenneth Ahola of Hibbing was chosen secretary. Dr. M. J. McKenna of Grand Rapids is retiring president. Speaker for the scientific session was Dr. Erick Leppo of Duluth, who talked on "Toxoplasmosis."

SAFETY CLINIC HELD IN SAUK CENTRE

Farm and highway accidents, their cause and prevention, were studied at a six-county safety clinic held in December at Sauk Centre. Speaking at the clinic, the first such area-wide program, were Dr. H. H. Young of the Mayo Clinic, Rochester, who spoke on "The Seriousness of Farm Accidents"; Earl M. Larimer, director of highway safety with the State department of highways, who talked on the topic, "Your Responsibility in Traffic." The program was sponsored by the Sauk Centre Safety Council and the Citizens Advisory committee.

ST. LOUIS COUNTY SOCIETY MEETS

Dr. A. J. Bianco, Sr., of Duluth, was named president-elect of the St. Louis County Medical Society at the December meeting of the group. Dr. Bianco will serve in 1956. Installed as president for 1955 was Dr. K. R. Fawcett, Duluth, who succeeds Dr. Sam Boyer, Jr., Duluth. Elected vice president was Dr. Paul Reed of Virginia. Dr. J. E. Haavik, Duluth, was named secretary-treasurer. Dr. K. E. Johnson, Duluth, was elected to the society's Advisory Committee, where he will serve with Drs. M. J. Fellows and J. J. Coll, both of Duluth. On the State Advisory Committee will be Drs. Boyer, C. M. Bagley and P. F. Eckman, all of Duluth. New members of the Judiciary Committee are Drs. A. G. Athens, G. C. MacRae, and D. W. Wheeler, all of Duluth, who were elected for 1957. Serving in 1955 will be Drs. Richard Bardon, F. H. Magney and L. W. Morsman, Duluth, and serving in 1956 will be Drs. A. J. Bianco and F. J. Hirschboeck, of Duluth, and F. R. Kotchevar of Eveleth. On the Economics Committee new members are Drs. M. G. Fredricks, H. O. Hoff and O. E. Sarff, all of Duluth. The 1955 committee is made up of Drs. E. C. Bagley and J. J. Coll, Duluth, and L. W. Johnsrud, Hibbing, with Dr. C. M. Bagley and P. G. Boman, Duluth, and Paul Reed, Virginia, serving in 1956.

Grievance Committee members are: Drs. J. C. Feuling, Duluth, and M. J. McKenna, Grand Rapids, 1957; Drs. L. L. Merriman, Duluth, and R. H. Puumala, Cloquet, 1955; and Drs. M. G. Gillespie, Duluth, and P. S. Rudie, Duluth, 1956.

The society elected Dr. R. P. Buckley, Duluth, as 1957 delegate, with Dr. Josiah Fuller, Duluth, as alternate. Delegates in 1955 will be Drs. Gillespie and MacRae, with Drs. P. G. Boman and R. C. Pedersen, Duluth, as alternates. In 1956 Drs. Clarence Jacobson, Chisholm, and W. S. Neff, Virginia, will be delegates, with Drs. J. K. Butler, Cloquet, and G. M. Erskine, Grand Rapids, as alternates.

TRI-COUNTY MEDICAL SOCIETY ELECTION

Dr. Donald E. Dille of Litchfield was elected new president of the Kandiyohi-Swift-Meeker County Medical Society at a recent meeting in Willmar. He succeeds Dr. R. P. Griffin of Benson. Dr. Harold Wilmot and Dr. Karl Danielson, both of Litchfield, were named as delegate and alternate, respectively, to the Minnesota State Medical Association meeting.

WOMAN'S AUXILIARY

(Continued from Page 68)

RAMSEY COUNTY REPORTS ACTIVITIES

Chairman of Medical and Surgical Relief, Mrs. H. F. Schroeckenstein, reports the packing and sending of twenty-six cartons of medical supplies in November to the Central Conference of the United Lutheran church. In December the same committee sent 22 cartons to the Maryknoll Missions.

Mrs. Harold F. Flanagan represented the Auxiliary at a meeting in November of the Woman's Auxiliary to the Jewish Home for the Aged for the Northwest.

On December 7, Mrs. J. E. Teisberg and other auxiliary members staffed Christmas seal booths in the downtown stores and public buildings. Judging of Tuberculosis Essays for high school students took place on November 17, and Radio Project awards were presented to Judy Lewis, local junior winner, and to Joan Lachenmayer, local senior winner, both of St. Agnes High School. State winners were Judy Lewis, first place in the junior division, and Barbara Sitzman, first place in the senior division. Miss Sitzman is also from St. Agnes High School. The essays were read at the January meeting of the Auxiliary. A film on rehabilitation was shown. The auxiliary also elected a nominating committee at this meeting.

Mrs. L. T. Simons

Of General Interest

Dr. Elizabeth B. Jerome and **Dr. Henry P. Staub,** both of Minneapolis, have been elected to fellowships in the American Academy of Pediatrics.

* * *

A display of old medical instruments used by pioneer physicians of Itasca County has been prepared for a historical room in Grand Rapids by **Dr. M. J. Schirber**, Grand Rapids. The historical collection is sponsored by the Itasca County Historical Society and the Old Settlers organization. Medical instruments used by **Dr. Thomas Russell** and **Dr. H. E. Binet** are among those displayed.

* * *

A number of Minnesota physicians attended sessions of the 40th annual clinical congress of the American College of Surgeons in Atlantic City, New Jersey, in November. Rochester doctors who were on the program included **Drs. J. M. Waugh, O. S. Culp, H. K. Gray, J. W. Henderson, H. J. Moersch, J. L. Bollman, J. B. Erich, G. A. Hallenbeck, K. A. Lofgren, C. A. Owen, Jr., J. C. Cain, O. H. Beahrs, B. Marden Black, W. H. Hollinshead, R. K. Ghormley, J. C. Ivins, E. H. Soule** and **H. H. Young.** Also in attendance were **Drs. E. A. Banner, J. H. Grindlay** and **J. W. Kirklin**, all of Rochester, **Dr. David J. Sanderson** of Fergus Falls, **Dr. Robert R. Cooper** of Minneapolis, and **Dr. R. F. Hedin** of Red Wing.

* * *

Representing the Minnesota State Medical Council at sessions of the North Central Medical Conference at St. Paul in November was **Dr. C. L. Oppegaard** of Crookston. The conference is made up of membership from Iowa, Minnesota, Nebraska, North and South Dakota and Wisconsin. Dr. Oppegaard, with Mrs. Oppegaard, also attended the interim meeting of the American Medical Association in Miami, Florida.

* * *

Dr. Paul M. Brickley, formerly a consultant in the Department of Ophthalmology, Mayo Clinic, has joined the staff of the Sansum Clinic, Santa Barbara, California.

* * *

The American Academy of Pediatrics, Chicago, has announced the election to membership of **Dr. Robert O. Bergan** of the Duluth Clinic.

* * *

Capt. I. L. V. Norman, former Willmar resident, has been selected for promotion to rear admiral. Admiral Norman commands the United States naval hospital at Great Lakes, Ill. He is a graduate of the University of Minnesota, and has been on active duty since receiving his medical degree in 1927.

* * *

Dr. A. E. Ritt, has been elected president-elect for 1956 of the Ramsey County Medical Society. President for 1955 is **Dr. Harold F. Flanagan. Dr. E. C. Gibbs** has been named secretary-treasurer for 1955. Retiring president is **Dr. Wallace P. Ritchie.**

* * *

Three Northfield physicians have been reappointed to the Rice County nursing board by the county board of commissioners. Reappointed members include **Dr. Robert F. Mears, Dr. Donald H. Petersen** and **Dr. Leonard Aamodt.**

* * *

Speaker at the interim scientific session of the American Trudeau Society recently in New York City was **Dr. R. D. Miller** of Rochester.

* * *

Seven Minnesota medical men have been made Fellows of the American College of Surgeons. The induction ceremony took place at the group's five-day clinical congress in Atlantic City. Nearly 1,000 surgeons were made Fellows in the Academy, which is the world's largest organization of surgeons. Minnesotans inducted include **Dr. William C. Bernstein,** St. Paul; **Dr. Manuel R. Binder, Dr. Llewellyn E. Christensen, Dr. Robert R. Cooper** and **Dr. Owen F. Robbins,** all of Minneapolis; **Dr. Josiah Fuller** of Duluth, and **Dr. David J. Sanderson** of Fergus Falls.

* * *

Dr. C. S. Bossert, Mora physician, was honored at a dinner last month sponsored by the Mora Commercial and Civic clubs. Dr. Bossert has completed more than 40 years of service in Kanabec county and the surrounding area.

* * *

Dr. Daniel H. Bessesen, Buffalo Lake, formerly Minneapolis physician, has been elected chief of the medical staff of Renville County Hospital at Olivia.

* * *

A member of a panel discussing cardio-pulmonary laboratory work at the eighth Postgraduate Assembly in Anesthesiology at the Hotel New Yorker last month was **Dr. H. F. Helmholz, Jr.** of Rochester, associate professor of physiology in the Mayo Foundation.

* * *

At home on Crystal Bay, Lake Minnetonka, are **Dr. and Mrs. Winston Rudolph Lindberg.** Mrs. Lindberg is the former Larey Evans, daughter of **Mr. and Mrs. Walter Sale Evans** of Mendenhall, Mississippi. Dr. Lindberg's parents are **Dr. and Mrs. Arvid C. Lindberg** of Minneapolis. Dr. Lindberg has practiced in Minneapolis since his graduation from the University of Minnesota Medical School.

* * *

Dr. H. J. Moersch presented a paper at the interim session of the College of Chest Physicians. The meeting was held in conjunction with the semiannual meeting of the board of regents of the College in Miami Beach in December. Dr. Moersch also gave a paper before the Cuban chapter of the American College of Chest Physicians meeting in Havana.

* * *

Dr. Grant L. Garlock has announced the opening of offices for the general practice of medicine and surgery at 509½ Beltrami Avenue in Bemidji.

* * *

Dr. Willard White of Minneapolis addressed the Scott-Carver County Medical Society at its December meeting at Shakopee. The subject of Dr. White's talk was "Intramedullary Fixation of Fractures."

* * *

Dr. W. F. Maertz, formerly of St. Paul, has been a staff member of St. Peter State Hospital at St. Peter, Minnesota, since June, 1954.

* * *

Dr. C. H. Mead and **Dr. E. I. Parson,** who have been associated for a number of years in the practice of general surgery in Duluth, have announced the formation of a partnership for continuation of their practice.

* * *

At the annual meeting of the Park Region District Medical Society held at the River Inn, Fergus Falls, in December, 1954, the guest speaker was **Dr. Merrill D. Chesler** of Minneapolis. His topic was "Skin Grafts and Flaps in Reconstructive Surgery."

* * *

Recently certified as a specialist in orthopedic surgery by the Royal College of Surgeons of Canada is **Dr. A. Ross Lerner** of Minneapolis. Dr. Lerner recently passed the oral and written examinations held in Canada.

* * *

Among Minnesota physicians attending an interim session of the American Medical Association in Miami, Florida, recently were **Dr. Jack Delmore** of Roseau, **Dr. R. R. Wright** and **Dr. F. H. Rosenthal** of Austin and **Dr. E. R. Hudec** of Echo.

* * *

Dr. John A. Anderson, a University of Minnesota graduate and professor of pediatrics at Stanford University, has been named head of the University of Minnesota pediatrics department to succeed **Dr. Irvine McQuarrie.** Dr. McQuarrie, who taught the new department head his specialty, will devote his time to medical training and research. Dr. Anderson is a native of Sioux Falls, South Dakota, and is a member of nearly a dozen medical and professional organizations, a diplomate of the national medical board and of the American Board of Pediatrics and a writer and editor in the pediatric field.

* * *

Captain Raymond J. Lindeman, Air Force medical officer and commanding officer of the 615th Infirmary at Ent Air Force Base, has received his flight surgeon's wings. Captain Lindeman is a graduate of the University of Tennessee, and took specialized training at the School of Aviation Medicine at Randolph Field, Texas.

Dr. James Thomson of Austin recently attended a reunion at Cook County Hospital in Chicago. Dr. Thomson took four years of study and training in obstetrics and gynecology at the University of Chicago Lying-in-Hospital and Cook County Hospital.

* * *

Featured speaker at Minnesota Farm and Home Week activities this month at the University of Minnesota was **Dr. Walter C. Alvarez,** former Mayo Clinic staff member and medical writer and lecturer. Other prominent speakers included Governor-elect **Orville L. Freeman** and **Ezra Taft Benson,** secretary of agriculture.

* * *

Dr. R. B. Skogerboe of Karlstad has made plans to take a year of graduate work in surgery at Abbott Hospital, Minneapolis. Dr. Skogerboe will continue his work with **Dr. B. R. McHardy** at the Karlstad Clinic.

* * *

A number of Mayo Clinic staff members presented papers before various groups in December. **Dr. L. M. Eaton** participated in the National Conference of the Myasthenia Gravis Foundation at the University of Pennsylvania School of Medicine in Philadelphia and **Drs. R. G. Bickford** and **H. M. Keith** presented a combined paper at the meeting of the American League Against Epilepsy in New York City. **Dr. A. G. Karlson** gave a paper as part of the short course on diseases of laboratory animals, which was given by the Armed Forces Institute of Pathology in Washington, D. C.

* * *

A Minneapolis surgeon and former president of the Minnesota State Medical Association, **Dr. O. J. Campbell,** has been named to succeed **Dr. Arthur A. Zierold** as chief of the surgical staff at Minneapolis General Hospital. Dr. Zierold resigned in November.

* * *

Dr. C. A. McNeely, who recently opened private practice in Herman, has closed her offices. She has announced no future plans.

* * *

A Waseca physician since 1951, **Dr. S. T. Normann,** has purchased the medical offices of **Dr. H. M. McIntire** of Waseca, who retired last summer. Dr. Normann has had his offices with **Dr. B. J. Gallagher** and **Dr. R. D. Davis.**

* * *

Ten members of the Mayo Clinic staff were among those attending the joint meeting of the American Academy of Obstetrics and Gynecology and the Sixth Annual American Congress of Obstetrics and Gynecology in Chicago in December. **Dr. L. M. Randall,** program chairman, led a conference and **Drs. E. A. Banner, J. E. Faber, M. E. Giffin, J. S. Hunter, Jr.** and **J. H. Pratt** conducted conferences and led round-table discussions. Drs. Faber, Giffin and Hunter presented papers and **Dr. A. B. Hunt** attended a meeting of the section officers. Others attending were **Drs. C. E. Johnson, M. E. Mussey** and **R. A. Smith.**

Dr. T. S. McClanahan has been named chief of staff at St. John's Hospital for 1955. **Dr. R. W. Emmons** was elected first vice chief and **Dr. P. G. Polski**, second vice chief. **Dr. J. W. Strand** was named secretary-treasurer of the staff. Also named to the executive committee for a three-year term at the December staff meeting were Dr. Polski and **Dr. F. J. Plondke.**

* * *

Some 1,000 friends honored **Dr.** and **Mrs. M. A. Burns** of Milan on their fiftieth wedding anniversary December 21. The open house was held at the Kviteside Lutheran church, Milan. Dr. Burns, now over eighty years old, is still in active practice in Milan, where he and his wife have resided for over fifty years. For the past several years Dr. Burns has been associated with his son, **Dr. Floyd M. Burns.**

* * *

Five Mayo Clinic staff men attended the December session of the Radiological Society of North America in Los Angeles. Conducting courses were **Dr. D. S. Childs, Jr.** and **Dr. G. D. Davis. Dr. J. R. Hodgson** presented a paper and an exhibit. Also in attendance were **Dr. C. B. Holman** and **Dr. Martin VanHerik.**

* * *

Recently named to the board of governors of the Minnesota Society of Obstetrics and Gynecology was **Dr. Jack R. Pierce** of the Lenont-Peterson Clinic in Virginia. Dr. Pierce also presented a paper on infant mortality in Virginia at the December meeting of the Society.

* * *

Fourteen members of the Mayo Clinic staff attended the interim session of the American Medical Association in Miami last month. Among those attending meetings of the House of Delegates were **Drs. E. V. Allen, J. A. Bargen, F. H. Krusen, L. A. Buie** and **R. R. Kierland.** Dr. Buie is also a member of the Judicial Council and chairman of the Council on Constitution and By-laws. Presenting exhibits at the meeting were **Dr. T. T. Myers, R. L. Parker, H. F. Polley** and **E. W. Johnson Dr. J. L. Emmett** presented a paper. Also at the meeting were **Dr. Victor Johnson,** a member of the Council on Medical Education and Hospitals, and **Drs. W. McK. Craig, J. W. DuShane** and **N. O. Hanson.**

* * *

Dr. E. C. Sargent of the Austin Clinic attended a meeting of the American Congress of Maternal Welfare last month at the Palmer House in Chicago. Dr. Sargent was also formally inducted into the American Academy of Obstetrics and Gynecology.

* * *

Dr. Robert R. Kierland, dermatologic consultant at the Mayo Clinic, Rochester, has been elected assistant secretary-treasurer of the American Academy of Dermatology and Syphilology. The group met last month in Chicago. Dr. Kierland is also associate professor of dermatology in the Mayo Foundation at the University of Minnesota graduate school.

* * *

Convalescing at his home in Browerville is **Dr. A. J. Lenarz,** who was a patient in St. Paul since he had a heart attack several months ago. **Dr. Joseph Brennan,** resident at St. Luke's Hospital, St. Paul, has taken over Dr. Lenarz' practice temporarily.

* * *

At a meeting in December of the Hastings Memorial Hospital medical staff, **Dr. N. J. Kulzer** was named staff president and **Dr. H. T. Fasbender,** secretary.

* * *

Mayo Clinic staff physicians attending the meeting of the American Academy of Dermatology and Syphilology in Chicago last month were **Dr. L. A. Brunsting,** member of the Committee on Education, **Dr. H. Montgomery,** chairman of the Committee on Pathology, **Dr. B. L. Lewis, Dr. R. R. Kierland, Dr. W. F. Kvale, Dr. P. A. O'Leary** and **Dr. H. O. Perry.** Dr. Brunsting led an informal discussion group and conducted a symposium and Dr. Montgomery gave an instructional course and presented an exhibit prepared with Dr. Lewis. Others appearing on the program were Drs. Kierland, Kvale and O'Leary.

* * *

Dr. Adelaide M. Johnson was in New York last month to attend a meeting of the American Psychoanalytic Association. She served as chairman of a panel discussion on psychotherapy.

* * *

Dr. Leonard A. Lang of Minneapolis was elected president of the Minnesota Obstetrical Society at its meeting December 4. **Dr. Rodney F. Sturley** of Saint Paul was elected vice president, and **Dr. Edward A. Banner** of Rochester was named secretary-treasurer.

* * *

After a wedding trip to New Orleans, **Dr. and Mrs. Gordon J. Vosti** are at home in Saint Paul. The bride is the former Marcia Jean Williams of Saint Paul. Dr. Vosti, formerly of California, is on the staff of Minneapolis General Hospital.

* * *

Newly-elected chief of staff of Asbury Methodist Hospital is **Dr. Wayne S. Hagen.** Dr. Hagen succeeds **Dr. P. J. Preston. Dr. Einer Monson** was elected vice president, and **Dr. M. Elizabeth Craig** was chosen secretary-treasurer.

* * *

Dr. Robert Delmore left Roseau for Louisiana, December 27, to do postgraduate study in surgery in New Orleans.

* * *

Two Mayo Clinic staff members were recently named to posts on national medical boards. **Dr. D. A. Boyd** was re-elected secretary-treasurer of the American Board of Psychiatry and Neurology at its annual meeting in New York City. **Dr. F. P. Moersch** was appointed to represent the American Board of Psychiatry and Neurology on the advisory board for Medical Specialties.

* * *

Dr. Meyer Z. Goldner is the new president and chief of staff at Mount Sinai Hospital for 1955, succeeding **Dr. B. I. Saliterman.** Other new officers are: **Dr. Reuben Berman,** vice president, and **Dr. E. B. Cohen,** secretary-treasurer.

Dr. Earl Hill will be chief of the service for medicine; **Dr. Norman Bloom,** surgery; **Dr. Arnold Anderson,** pediatrics, and **Dr. Melvin Sinykin,** obstetrics and gynecology. **Dr. Manuel Binder** and **Dr. John LaBree** are newly-elected members of the executive committee.

* * *

Host to staff and board of directors of Union Hospital at New Ulm for their annual Christmas party was **Dr. F. H. Dubbe.**

* * *

Dr. Owen H. Wangensteen, chief of the Surgery Department and professor of surgery at the University of Minnesota, has been named one of ten recipients of the 1955 *Modern Medicine* Award for Distinguished Achievement. Announcement of his selection was made by Dr. Walter C. Alvarez, editor in chief of *Modern Medicine* magazine.

Dr. Wangensteen's award is the result of his research in technical surgery and his development of educational programs in the field of surgery. The cross-circulation operation, eliminating the need for heart-lung machines in heart surgery, was developed at the University of Minnesota under his direction.

The award is the only one that represents the opinions of members of the medical profession. The annual awards are made in recognition of significant contributions to medical science and the nation's health.

* * *

At the December meeting of the **Medical Staff of Glenwood Hills Hospital and Homewood Hospital,** the following officers were appointed for 1955: President and chief of staff, Irving C. Bernstein, M.D.; vice president, John Schumacher, M.D., and, secretary-treasurer, J. C. L. Peteler, M.D.

NEW LOCATIONS

Dr. J. A. Abbullarade, a former resident of San Salvador, has joined the staff of the Cokato hospital as an associate of **Dr. Theodore Greenfield.** Dr. Abbullarade previously was at Eitel, Fairview and Maternity hospitals in Minneapolis.

* * *

Dr. William D. Misbach of Fairmont has accepted a residency at the University of California at Los Angeles. He will train in pediatrics. Dr. Misbach was graduated from the University of Minnesota School of Medicine and interned at Wesley Memorial hospital in Chicago.

* * *

Dr. Allen W. Wittchow, who has practiced ophthalmology in St. Paul, has joined the staff of the Quain and Ramstad Clinic in Bismarck, North Dakota. A graduate of the University of Wisconsin Medical School, Dr. Wittchow interned at General hospital, Minneapolis, and completed a three-year fellowship at Mayo Clinic.

Dr. Thomas Kemp, a graduate of the University of Minnesota School of Medicine, has joined the medical offices of **Dr. G. A. Cooper** and **Dr. C. W. Stoops** in Madison, Wis. He will specialize in dermatology. Dr. Kemp interned at St. Luke's hospital, Duluth, and did postgraduate work at the University of Pennsylvania and at the Philadelphia skin and cancer hospital.

* * *

Dr. William J. Hultgen, who was located at 939 Lowry Medical Arts Building, St. Paul, is now engaged in the practice of ophthalmology at 7809 Herschel Avenue, La Jolla, California.

* * *

Dr. Warren H. Ruchie, a resident of Racine, Wisconsin, for the past two years, has become associated with **Dr. William Macklin, Jr.,** in the practice of radiology at Willmar. Dr. Ruchie, a graduate of the St. Louis University School of Medicine, interned at St. Mary's hospital, and is a Diplomate of the American Board of Radiology.

* * *

Dr. Kermit Stensgaard, who practiced medicine in Thief River Falls from 1946 to 1948, has returned to the city to become affiliated with the Falls Clinic. Dr. Stensgaard was a resident in surgery at Wayne University Hospital, Detroit, in 1948 and served in the Navy until recently.

MINNESOTA BLUE CROSS—BLUE SHIELD

The famous Blue Cross—symbol of the finest in hospital care protection to one out of every four Americans—has been assigned a new protective role. To protect you on the road, this emblem is covered in a highly-reflective material that can be seen for a distance of half a mile under head-light beams. Attached to the rear bumper of your car, it can mean life-saving protection if your tail light fails. When you are parked, the emblem's brilliant glow gives approaching motorists ample warning. Night or day, this Blue Cross emblem on your car gives you an added measure of safety and security.

Blue Cross will be happy to furnish you and your associates with emblems without cost or obligation. You can obtain an adequate number of free emblems by dropping a card or letter to the Blue Cross office.

Throughout the first month during which Blue Shield field representatives have been fully active in the Professional Relations programs, visits have been made to the offices of approximately 600 doctors in the Twin Cities and the surrounding area.

The principal purpose of this program is one of service to the doctors. Through the discussion of mutual problems which arise, more information about Blue Shield is furnished the doctors and their office personnel. In the reports submitted by the Blue Shield field representatives engaged in this work, questions have arisen about consultation services, diagnostic x-ray benefits when the x-rays are directly related to in-hospital medical care, surgery or obstetrical services, the meaning of the term "emergency medical care," which is defined in the contract as medical services required when the condition for which the patient is hospitalized places the patient's life in immediate and serious danger. Other inquiries have related to the information necessary in presenting a claim for payment by Blue Shield. In the latter, the result of this program of service may ultimately eliminate many problems which affect the prompt payment of claims.

Complete and detailed records are being maintained, including any recommendations made by doctors regarding the administration of Blue Shield and proper liaison between Blue Shield and the doctor or his staff. In view of the fact that the program has been so well received in the Twin Cities, it is being expanded to cover the doctors outside of the Twin City area. Having found the program to be beneficial both to the doctors and to Blue Shield, the field representatives are now going in the other areas of the state. With the co-operation of the members of the medical profession, a mutual understanding and resulting improved administration should result from this program.

DIAGNOSIS OF CORONARY HEART DISEASE

(Continued from Page 55)

put the greatest reliance. Extensive cardiovascular research is presently being done to ascertain the etiology of atherosclerosis. Ultimately the pieces of this puzzle will fall into place, and the completed picture will emerge. When the etiology becomes apparent, appropriate diagnostic as well as better prophylactic and therapeutic measures should also become available.

Original Contributions

Hypothermia in Cardiac and General Surgery

F. JOHN LEWIS, M.D.

Minneapolis, Minnesota

THE intricate control system which maintains body temperature within a narrow range is amazingly effective in a wide variety of environmental situations. Without this control, optimum function of the internal metabolism and long survival is impossible, yet for relatively short intervals, normal regulation may be purposely overcome and the body temperature may be significantly reduced without permanent harm. There is during this period of lowered temperature a striking reduction of the general metabolic rate which makes it possible to occlude the blood flow to all or any part of the body for a much longer period of time than is possible at normal temperatures. Thus, time is provided to do some types of surgery in an open, bloodless field—an advantage which has proven to be useful in intracardiac surgery and in surgery of the great vessels. The bloodless field made possible by hypothermia may also prove to be a worthwhile advantage in doing extensive operations for cancer. Furthermore, a moderate degree of hypothermia has been advocated for poor risk patients who must undergo surgery and it is possible that critically ill, hyperthermic patients may be benefited by a drastic reduction in their body temperature.

In this article the author will attempt to summarize, briefly, some of the provocative new uses of hypothermia, which are still mostly experimental, largely in the light of his own interest and experience.

Open Intracardiac Surgery

Bigelow[2] and independently, Boerema,[3] were the first to demonstrate experimentally that hypothermia makes it possible to operate within the open heart by means of a simple technique. With the body temperature reduced the total inflow to the heart may be occluded and then any chamber may be opened long enough to perform deliberate operations under direct vision. If this is attempted without lowering the temperature, the period of occlusion must be too short for practical use or else the central nervous system, and possibly the heart will be damaged. Hypothermia, by providing sufficient time, has made this uncomplicated way of working within the heart practical for patients as well as for the experimental laboratory.

Technique.—In patients who are to undergo intracardiac surgery for the repair of atrial septal defects[7], anesthetic induction with pentothal and curare precedes the actual cooling. The extremity leads of a cardioscope are fixed in position and a continuously recording rectal thermometer is adjusted. After this preparation, the cooling is started by wrapping the subject in a rubberized cover through which an alcohol solution kept at 25° F. is circulated. A period of one to two and a half hours is needed to lower the body temperature to 29.5 degrees C. (85 degrees F.). Then the temperature of the cooling blankets is raised, the chest is exposed, and the operation is begun, but the body temperature will continue to fall slowly for another hour reaching a low point of about 26 degrees C. (81 degrees F.).

The chest is opened, through an anterior incision with transverse division of the sternum and entry into both pleural cavities at the fourth interspaces. This provides excellent exposure for the exploration and repair. Exploration of the heart is carried out first before the open repair is done by inserting a finger through an opening in the right auricular appendage. By this means the surgeon obtains an understanding of the pathological anatomy which allows him to plan the precise type of repair that will be used.

From the Department of Surgery, University of Minnesota, Minneapolis.

This investigation was supported by Research Grant H-1374 of the National Heart Institute of the National Institutes of Health, Public Health Service, and by Grants from the University of Minnesota Graduate School, and the Minnesota Heart Association.

Just before the right atrium is opened, the channels to and from the heart are occluded. The superior and inferior vena cavae are closed first, then after a few beats, loops of tape are tightened around both pulmonary roots occluding the pulmonary veins, and finally a clamp through the transverse sinus of the heart is closed to shut off the aorta and pulmonary artery. The aorta is occluded to prevent air embolism while the heart is open.

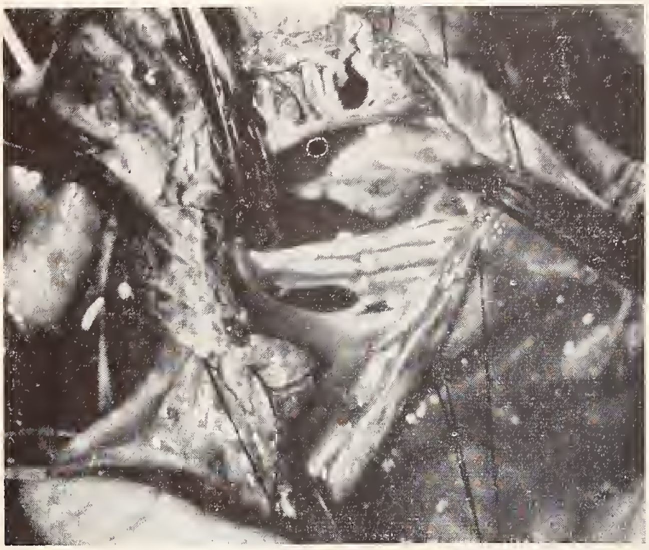

Fig. 1. Photograph of the open right atrium while the vascular inflow and outflow are occluded. The metal suction tip is placed within the atrial septal defect. Suture repair is about to begin. The head of the patient is to the left.

With the right atrium open, the septal defect is closed with continuous or interrupted silk stitches (Fig. 1). Just as the last stitch is tied the air is washed out of the left atrium by running saline into it through a small tube lying in the defect. This tube is removed as the repair is completed. Before closing the heart, air is evacuated from the right atrium by partially releasing the inferior vena cava thus allowing the atrium to fill with blood. The atrial wound is closed with a clamp and circulation is resumed. Finally, the atrial wound is sutured with a continuous silk stitch. In our human patients the circulation has been interrupted from four to eight minutes.

By the time the chest is being closed the rubberized blankets covering the patient have reached a temperature of 45 degrees C. and the body temperature may have started to rise. This warming-up process is accelerated, after the skin has been sutured, by immersing the patient in a bath of hot water at 45 degrees C. (114 degrees F.). In thirty minutes to one hour the body temperature will have reached 90 to 95 degrees F., and the patient is then removed from the water.

At the time we wrote about our early experience with this method,[7] eleven patients with atrial septal defects had been operated upon with two deaths. Now twenty-two patients with this type of defect have undergone surgery and there have been no additional deaths. The oldest, a survivor, was fifty-two.

This technique is a good one for repairing defects of the atrial septum, but it is not yet clear whether this or one of the other methods of closing these defects will prove to be the best. In any case, it is evident that this type of congenital heart disease is now curable.

Success in operating upon the atrial septum has been a stimulus to test the technique on other regions of the intracardiac anatomy. We have found that hypothermia can be used experimentally to make and repair ventricular septal defects, [11,12] and to operate upon the various cardiac valves under direct vision. It is likely that some of these experimental operations can be adapted to the treatment of human heart disease. Until much simpler and more efficient heart-lung machines are invented or until cross-circulation can be employed with no risk to the donor, hypothermia will play an important part in the new field of open, intracardiac surgery.

Cancer Surgery

More than a decade ago general body cooling was used in a memorable experiment to treat patients with advanced cancer.[5] Though most of the patients withstood the prolonged cooling well, there were, unfortunately, no cures, and there was probably no significant retardation in the onslaught of the disease. Hypothermia failed then as a treatment of cancer but it may now turn out to be an aid in doing some types of cancer surgery.

The usefulness of hypothermia for this type of surgery is due to the fact that it permits a relatively prolonged occlusion of the blood supply to any large segment or organ of the body. The bloodless operating field thus created makes resections, which would otherwise be bloody and difficult, quite dry and easy.

After preliminary experimental work,[10] we have used hypothermia this way to do total right hepatectomies for metastatic or primary liver cancers (Fig. 2). The patients have been cooled as the cardiac patients were and after cooling the liver was exposed through a right, combined, thoraco-abdominal incision. After a preliminary clearing of the porta hepatis the blood flow to and from the liver was interrupted, and we were then ready to resect the liver. Blood flow was occluded by clamping the thoracic aorta above the diaphragm, the portal vein and the hepatic artery below the liver and the inferior vena cava both above and below the liver. In this way the entire right lobe could be resected with minimal blood loss and adequate time was provided to repair holes in the vena cava and to suture the open vessels in the substance of the liver before the circulation was restarted. The blood flow has been occluded during these operations for forty-five minutes without producing anoxic injury.

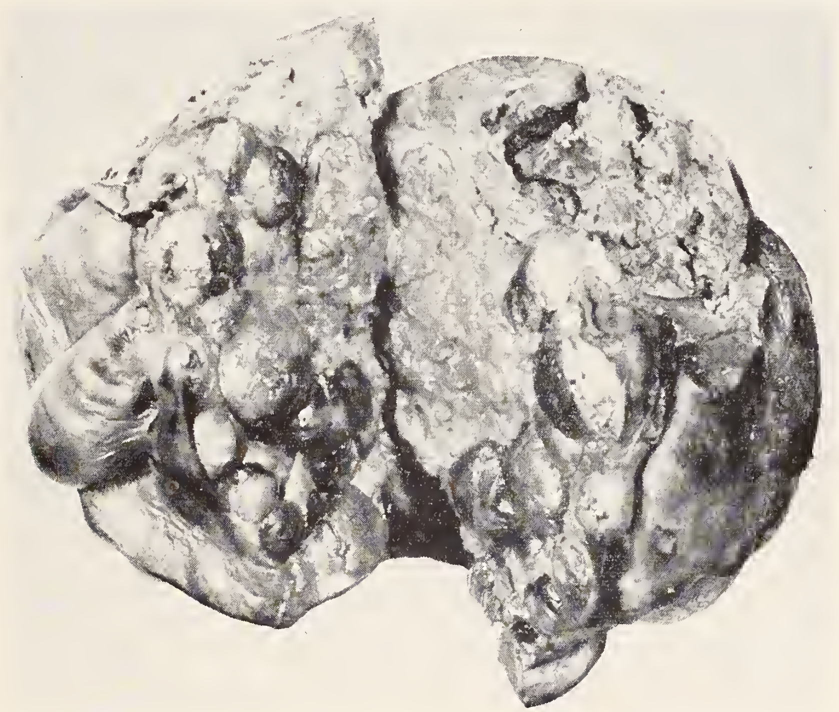

Fig. 2. Entire right lobe of the liver containing a large hepatoma which was removed during hypothermia. The patient was a nine-year-old boy. The gall bladder is seen attached to the surface at the left of the photograph.

Four right hepatectomies have been done this way. Two patients survived and there were two operative deaths, both of which were due to postoperative intra-abdominal hemorrhage which apparently started after the body temperature had returned to normal. One nine-month-old infant died a few hours after surgery of hemorrhage and a seventy-two-year-old man died three weeks postoperatively of an intra-abdominal abscess which appeared to be the late complication of hemorrhage.

The most recent patient who had a right hepatectomy during hypothermia was rewarmed before her abdomen was closed and post-operative hemorrhage did not occur. This seems to be the sensible way to avoid late hemorrhage. If it continues to be successful, hypothermia, plus high vascular occlusion, may prove to be a useful technique for doing extensive cancer operations, not only in the liver but in other areas of the body as well.

Surgery of the Aorta

General hypothermia has found a limited though distinct application for doing resections of the thoracic aorta.[4] Here again, as in intracardiac and cancer surgery, hypothermia allows a longer vascular interruption than is tolerated at normal body temperature. The abdominal aorta below the celiac and the renal arteries may be safely interrupted long enough at normal temperatures to remove an aneursym and stitch a graft in place, but in the thoracic aorta this may not be possible. A sufficient period of occlusion at the thoracic level to allow removal of a traumatic or syphilitic aneurysm and replace it with a graft, may lead to spinal cord damage. With the body temperature lowered, however, the period of occlusion that can be used safely is much longer. Cooling is not necessary when resecting a coarctation of the aorta and replacing it with a graft, for patients with this disease have an extensive collateral circulation which bypasses the obstruction.

Surgery in "Poor Risk" Patients

Bigler and McQuiston[1] in this country pioneered the use of hypothermia for "poor risk" children during heart surgery, but though the danger of an elevated temperature in these patients has been generally recognized, planned hypothermia as part of the anesthetic technique has not been widely adopted. Furthermore, at least in this country, moderate hypothermia has not often been tried for desperately ill patients who have to undergo other types of surgery. In Europe, on the other hand, Laborit[6] and other French surgeons, particularly, have advocated moderate degrees of hypothermia or "artificial hibernation" for weak, aged, or critically ill patients who must undergo major surgery. A combination of drugs called a "lytic cocktail" has been used with limited surface cooling to produce a slight reduction in body temperature prior to surgery.

Our own experience with this use of hypothermia has been limited but we have been impressed, nevertheless, with the ability of ill and aged patients to withstand surgery while their temperature was intentionally reduced. Frankly, however, it is not yet certain that hypothermia will help in bringing "poor risk" patients through major operations. To reach such a conclusion concerning this use of hypothermia or "artificial hibernation" a statistically controlled clinical study may be necessary and none, as yet, has been forthcoming.

Patients with Fever

Some effort to reduce the temperature of patients with high fever through the use of alcohol sponge baths, wet towels, and fans has long been a common practice. Such methods plus the use of antipyretics have been employed when the temperature, for any cause, has risen above 104 to 105 degrees F., and they have been abandoned again when the temperature has fallen to 102 degrees F. or lower. This treatment is often helpful but it may not have been carried far enough. There has not, for example, generally been a persistent systematic effort to reduce the temperature in these patients to normal or even subnormal levels and keep it there, yet such an effort may, we think, occasionally be strikingly beneficial. Certainly, the exhausting effect of a continuous fever with the racing metabolic rate that accompanies it may be crucially harmful and probably in no sense helpful.

This line of thinking has led us to use cooling in eleven seriously ill, feverish patients who have usually been suffering from postoperative complications. Chlorpromazine* plus sodium luminal was used initially for sedation and the patient was then placed on a large rubberized blanket containing a long rubber tube through which a cold alcohol solution was pumped (Fig. 3). In order to bring the temperature down it was usually necessary to cool the blankets to about 40 to 50 degrees F., but once the rectal temperature had reached a level of 95 to 97 degrees F. it could be kept there by maintaining the temperature of the blanket between 70 to 80 degrees F. Additional drugs were not always necessary after the temperature had fallen, and the patient could be kept at a normal or slightly subnormal temperature for days, if necessary, until, as cooling of the blanket was required no longer, it was evident that the tendency to fever had disappeared.

This is obviously merely palliative therapy and we have used it only for critically ill patients. It has, nevertheless, apparently been beneficial for several individuals. Of the eleven patients treated in this fashion five were apparently benefited and survived, three were helped temporarily but they finally died, and three succumbed without even temporary improvement.

Discussion

A few of the potential, clinical applications of hypothermia have been touched upon in this short report, but it would be highly presumptuous at this time, to conclude that hypothermia is going to be of lasting value in any of the ways described. Certainly, both regional and general hypothermia have turned out to be disappointing in the past after a calm evaluation stilled an early flurry of enthusiasm. It is possible that the uses of hypothermia listed here may also be superseded by other methods, or that they may for various reasons, never be accepted. It is true, even now, that many of the things that can be done with hypothermia can be done with other means, but possibly not so well nor so simply. Simplicity is clearly one of hypothermia's most attractive qualities.

---

*"Thorazine" distributed by Smith, Kline and French.

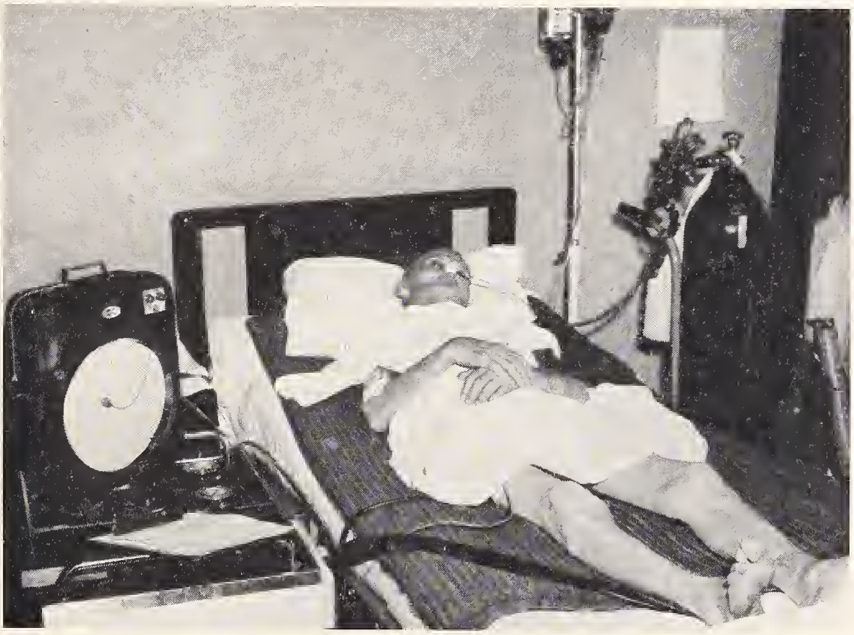

Fig. 3. This illustrates the technique used for cooling a hyperthermic patient. The rubberized blanket, cooled by the machine at the left, is seen beneath the patient. Usually this is covered with a single sheet. A rectal temperature recorder is placed on top of the refrigerating machine.

This quality of simplicity plus the other valuable characteristics of the technique have made it what is probably the best way at present to repair certain intracardiac defects under direct vision. For the repair of atrial septal defects and perhaps for other intracardiac anomalies the interval of blood flow occlusion allowed by moderate degrees of hypothermia is sufficient. Patients of a wide age range and various degrees of illness can successfully withstand this moderate degree of hypothermia.

For the future there is the challenge of trying to lower the level of safe, clinically practical, hypothermia. When temperatures significantly below those presently employed are possible, the method will doubtless have a wide new range of usefulness. This objective may soon be achieved for it is now possible to lower the temperature of rats and dogs down to a few degrees above freezing and revive at least some of them without sequelae.[8,9]

In this brief exposition there has been no space to try and describe the physiology of hypothermia, but this is just as well, for much that has been left unexplained is still unknown. A number of alluring pathways, each seemingly worthy of a long exploration, tempt the investigator of hypothermia; perhaps at least one of them will lead to a better understanding of this intriguing phenomenon.

Heredity of Diseases of the Heart, Blood Vessels, and Blood

RAY C. ANDERSON, Ph.D., M.D.
Minneapolis, Minnesota

DISEASES of the heart, blood vessels and blood constitute a large fraction of the organic ailments dealt with by the practicing physician. Usually of a serious nature, these diseases are frequently dependent in greater or lesser degree upon hereditary factors. Diseases having definite or possible genetic significance are shown in Tables I and II, with the more strongly hereditary conditions heading each list.

TABLE I. DISEASES OF THE HEART AND BLOOD VESSELS

Disease	Genetic Pattern
"Primary"	
Telangiectasia	Dominant
Congenital lymphedema	Usually dominant
Glycogen storage disease of heart	Probably recessive
Essential hypertension	Dominant factor (s)?
Rheumatic fever	Genetic susceptibility?
Congenital heart defects	Genetic factors?
Coronary heart disease	Genetic factors?
"Secondary"	
Arachnodactyly	Dominant
Friedreich's ataxia	Recessive
Myotonia dystrophica	Dominant
Muscular dystrophy	Several genetic types
Mongolism	Genetic factors?

"Primary" Types

Telangiectasia, an anomaly of the small blood vessels, is a well-known dominant trait whose presence is usually first heralded by nosebleeds. Not so widely known is the occasional occurrence of pulmonary arterio-venous fistulae as part of the clinical picture.

Congenital lymphedema, or Milroy's disease, is an uncommon anomaly of the lymph vessels which generally follows a dominant pattern of inheritance.

Glycogen storage disease of the heart is a rare and fatal abnormality of the heart in infants which is usually diagnosed only after death. Its occurrence in siblings has strongly suggested a recessive mode of inheritance. It is not to be confused with the hepatic type of glycogen storage disease, also probably a recessive genetic disease.

Essential or primary hypertension constitutes one of the most common chronic diseases in the adult population. Its familial occurrence has long been recognized, and a dominant mode of inheritance has been suggested by some workers in view of its frequent appearance in successive generations. However, its clinical features vary greatly, probably due to a variety of complicating environmental factors. Genetic analysis of this trait in populations is complicated by the variation in clinical picture, confusion with secondary types of hypertension, and the possibility of its not being a single entity.

Rheumatic fever, with its frequent heart involvement, is another of the common diseases with a well-recognized familial tendency. Innumerable genetic studies have been reported, with a variety of results and conclusions. Some of these appeared before, some after, the relatively recent finding that streptococcal infection is the immediate precipitating factor for an attack of rheumatic fever. Thus, the problem consists of determining whether the distribution of rheumatic fever cases is merely a random event (rheumatic fever is said to follow approximately 3 per cent of Group A

From the Department of Pediatrics and Dight Institute of Human Genetics, University of Minnesota, Minneapolis, Minnesota.

Adapted from author's contribution to symposium on clinical genetics at meetings of American Society of Human Genetics, Gainesville, Florida, Sept. 8, 1954.

beta hemolytic streptococcal infections), is determined by environmental factors, or whether it depends upon hereditary susceptibility of either a specific or general nature. The answer to this question awaits the development of biochemical studies, but present evidence suggests that susceptibility is at least partially dependent upon genetic factors.

TABLE II. DISEASES OF THE BLOOD

Disease	Genetic Pattern
Classical hemophilia	Sex-linked recessive
Afibrinogenemia	Recessive
Thalassemia	Recessive
Sickle-cell anemia	Recessive
Congenital hemolytic jaundice	Dominant
Hereditary nonspherocytic hemolytic anemia	Dominant
Ovalocytosis	Dominant
Pelger's nuclear anomaly	Dominant
Fanconi's anemia	Probably recessive
Pernicious anemia	Probable genetic factors
Polycythemia vera	Possible genetic factors
Familial neutropenia	Possible genetic factors
Familial eosinophilia	Possible genetic factors
Thrombocytopenia	Sometimes a genetic factor?
Leukemia	Sometimes a genetic factor?

Congenital heart malformations have recently been shown to have a fourfold increase in incidence in subsequent siblings of affected cases as compared to the general population. Other than this, and a known relationship to maternal Rubella in a small minority of cases, the etiology remains essentially unknown.

Coronary heart disease, like hypertension, is known to run in families, though to a less striking extent. Its occurrence is probably partially related to dietary factors, but the clarification of its exact etiology awaits further metabolic and chemical studies.

"Secondary" Types

Arachnodactyly, or Marfan's syndrome, is a dominant hereditary condition with a variety of striking clinical manifestations. The characteristic long slender limbs and digits have accounted for its name. Frequent eye involvement, with displacement of the lens, has made this condition well known to the ophthalmologist. Heart disease is also frequently associated. Formerly, the most common cardiac lesions were considered to be septal defects, but it is now agreed that medial degeneration of the aorta, often with aneurysm formation, is the typical cardiac manifestation of the disease. The syndrome illustrates beautifully the genetic phenomena of pleiotropy and variable penetrance.

Friedreich's ataxia has been viewed primarily as a disease of the central nervous system, even though some of the earliest case reports described myocardial changes. Cases simulating rheumatic and congenital heart disease are now being detected with increasing frequency by alert cardiologists familiar with its complete clinical picture. The disease generally shows a typical recessive type of inheritance.

Myotonia dystrophica, a dominant disease also familiar to the neurologist, sometimes shows myocardial changes. The same is true for the various genetic types of *muscular dystrophy* (dominant and sex-linked recessive forms).

Mongolism, one of the most common and best known types of mental deficiency (incidence of about one in 750 births), is considered by some to be partially dependent upon genetic factors, but its etiology remains essentially unknown. An association with increased maternal age has been reported by nearly all investigators. In 25 to 40 per cent of cases there are associated congenital heart defects, usually septal defects, but encompassing the whole spectrum of congenital heart anomalies.

Diseases of the Blood

Hemophilia still ranks as the best known of the hereditary diseases of the blood, having been the subject of countless articles in the lay press and continuing to be the classical example of sex-linked recessive inheritance in all textbooks of genetics. With the recent development of more precise tests for deficiencies in the clotting mechanism of blood there has been a critical review of cases which formerly would have been labeled merely as hemophilia or hemophilia-like disease. These studies have revealed a whole "family" of diseases. Classical hemophilia remains the most common type, yet clinical evidence suggests that this disease may represent a series of alleles, each producing disease of different severity. One of the proposed classifications, that by the group at the University of North Carolina,[1] is as shown in Table III. All of these diseases are bleeding disorders involving clotting abnormalities. Incidentally, the frequently asked question of whether hemophilia can occur in the human female can now be answered in the affirmative. A rather recent and remarkable finding has been the recognition of a disease in dogs simulating human hemophilia both in laboratory features and in genetic pattern.

TABLE III. HEMOPHILIA AND RELATED DISEASES

Disease	Genetic Pattern
Classical hemophilia (deficiency of antihemophilic globulin or AHG)	Sex-linked recessive allelic series
Hemophilioid state A (Parahemophilia or Owren's disease; deficiency of accelerator globulin or AcG	Probably dominant
Hemophilioid state B (deficiency of serum accelerator Factor or SAF)	Dominant
Hemophilioid state C (Christmas disease; deficiency of plasma thromboplastin component or PTC)	Sex-linked recessive
Hemophilioid state D (deficiency of plasma thromboplastin antecedent or PTA)	Probable genetic factor

Afibrinogenemia, another bleeding disorder which could well have been included in Table III, has proven to be as interesting as it is rare. Just as genetic theory requires of a very rare recessive trait, this condition involves cousin marriage in a high percentage of reported cases. Heterozygotes, or carriers of a single abnormal gene, show a reduced amount of fibrinogen, and can therefore be identified despite the absence of clinical symptoms.

Thalassemia, previously better known as Mediterranean anemia because of its higher incidence among Mediterranean peoples, is another recessive trait in which the heterozygote shows a lesser but definite effect. In fact, the homozygous condition has been termed thalassemia major, and the heterozygous condition has been called thalassemia minor. This situation raises the purely academic question of nomenclature, whether to designate the thalassemia gene as a recessive or a dominant.

Sickle-cell anemia is somewhat similar to the foregoing in its genetic features. The homozygote shows the full-blown disease, and the heterozygote ordinarily shows merely the sickling trait. Biochemical studies have shown the former to possess 100 per cent abnormal "s" hemoglobin usually, and the latter approximately 40 per cent. Sickle-cell anemia shows a marked racial predilection, being a disease almost exclusively of individuals with negro ancestry. Interaction between the sickle-cell gene and the thalassemia gene has been identified, resulting in a clinical condition resembling sickle-cell anemia. In addition, another abnormal hemoglobin, hemoglobin "c," has been identified, and has been found to have a similar genetic pattern. It appears that the current combined clinical-genetic-biochemical studies of the hemoglobins will reveal a whole series of genetically distinct but clinically related diseases.

Congenital (hereditary) hemolytic jaundice has been a favorite textbook example of dominant inheritance for many years. In addition, it has been used to illustrate the application of genetics to clinical medicine. Some bearers of the gene will suffer severe hemolytic crises, while others will remain asymptomatic. All cases can be identified by the presence of abnormal erythrocytes, spherocytes, with increased osmotic fragility as compared to normal erythrocytes. Since surgical removal of the spleen affects a clinical cure in this condition, splenectomy has been suggested as a prophylactic measure to be used in asymptomatic relatives who have been identified by family studies as carriers of the gene. In the past several years a new disease has been described, *hereditary nonspherocytic hemolytic anemia.* It resembles the previous disease in its genetic pattern, but it does not respond to splenectomy.

Ovalocytosis, or elliptocytosis, dominantly inherited, is a relatively uncommon anomaly of the red blood cells as implied by the name. The trait is of rather minimal clinical importance.

Pelger's nuclear anomaly, again a dominant trait, involves decreased segmentation of the nuclear material in the polymorphonuclear leukocytes.

Fanconi's anemia was first described several decades ago, but in recent years there has been a real influx of cases into the medical literature. The disease presents as a hypoplastic anemia together with a number of other varied signs, skeletal anomalies being among the more conspicuous. Its frequent occurrence in siblings suggests a recessive inheritance.

Pernicious anemia rates as one of the most celebrated of human ailments, having been the subject of some of the most brilliant of medical discoveries. Though its familial tendencies have long been recognized, its exact etiology and its basic or primary nature remain largely unknown.

Polycythemia vera, familial neutropenia, and familial eosinophilia have all been described as showing familial tendencies in some cases, just as the names suggest. However, the etiology of these conditions continues to be mainly a matter of speculation, and they may each be loose groupings of several entities.

Primary thrombocytopenic purpura has also been described as showing familial tendencies in some cases, but it is more interesting in its "pseudogenetic" features. Thus, women with this condition, whether splenectomized or not, can have infants who show a transient thrombocytopenia (low platelet count) during the first few weeks following birth.

Leukemia has been the subject of intensive investigation. As with the majority of malignancies, the etiology remains obscure. A few pedigrees suggest that hereditary factors may play a role in an exceptional case.

Many other disorders of the blood and vascular system have also been described as familial or hereditary, but usually the evidence rests on only a scattering of pedigrees. Moreover, the disorders themselves have often been rather poorly defined clinically. There is little doubt that new hereditary diseases of the blood will be identified, especially as progress is made in the field of blood proteins. Thus, pediatric cases of a recently recognized abnormality, *agammaglobulinemia,* may represent a sex-linked recessive gene. Even as it is, the currently known hereditary diseases will progressively attain greater clinical significance as those of environmental origin gradually come under medical control.

MONIES FOR MEDICAL SCHOOLS

The first 1954 distribution of unrestricted funds to the nation's eighty medical schools was made in July by the National Fund for Medical Education. These 1954 grants totalled $2,176,904.71, including $1,101,000 from the medical profession through the American Medical Education Foundation.

Each of the seventy-four four-year medical schools received $15,000 plus $25 per undergraduate medical student enrolled in the school. Each of the six two-year schools received $7,500 plus $25 per student. Added to these grants were gifts of individual doctors to designated schools.

Since 1951, nearly seven million dollars has been awarded to the country's medical schools—half of this total contributed by the medical profession. Fund grants, are used by the schools primarily to fill teaching vacancies, to create new faculty posts and to initiate courses in areas of recent scientific advances.

Psychiatric Aspects of Ulcerative Colitis

L. R. GOWAN, M.D.
Duluth, Minnesota

IT IS NOW generally accepted that emotional disturbances may produce functional and organic changes in various organs of the body. Repressed emotional conflicts, unfulfilled desires, long-standing deep frustrations, feelings of guilt and fears of one type or another are factors that frequently manifest themselves in the development of physiological and pathological alterations in the human body.

Emotionally conditioned illnesses are prevalent and widespread. Emotional factors frequently block the recovery of an illness that otherwise would respond to medical care more rapidly and more completely. The resolution of these emotional factors is necessary for the patient's recovery. Unless this is accomplished many patients may develop a chronicity of disabling, discomforting symptoms that produce a state of invalidism.

Psychiatric aspects implies behavioral aspects. Behavioral aspects includes all that has gone before in the way of life's experiences and the development and organization of man's defenses, with which to meet new situations, especially those that threaten his well-being. Behavior then, is a process of adaptation of the organism between physiological needs and external circumstances.

The dynamic approach to the understanding of human behavior and its relation to organic lesions, still meets with some resistance from physicians and students of medicine. This is somewhat understandable when one considers that psychiatry must, in a sense, compete with a more easily understood and more objective and tangible approach to disease, as demonstrated in those illnesses where known etiologic factors are present, laboratory data confirm a dysfunction and very real pathological tissue changes can be visualized. It is important, however, that the physician recognize that not only does the patient have a physical disease but that the patient is already possessed of behavior patterns to which the passing disease process has merely been added.

Physicians must not lose themselves in their consideration of the pathologic and bacteriological aspects of a disease, to the point where they lose sight of the meaningful data in the patient's life history. They must recognize that the patient's past experiences, his capacities and his motivation toward the future, all may serve as determining factors in the way in which he will react to any given organic process and also may be the deciding factor in the precipitation and continuation of a patho-physiological disturbance.

The importance of emotional factors in recovery from many physical diseases is now stressed by medical schools throughout the student's entire training. Most physicians are now thoroughly conditioned to the recognition of the inseparability of mind and body. The application of this knowledge has aided greatly in the treatment of psychosomatic disorders. To lose sight of the emotional factors means losing an important contribution to the patient's welfare.

Ulcerative colitis is one of many illnesses having emotional disturbances as a factor in their etiology. It is a disease that is notoriously resistant to treatment and is severely disabling. Unresolved emotional problems delay and may prevent recovery in this condition. There are three phases of treatment: medical, surgical and psychiatric. All three are important. All three must be given careful consideration in the treatment program.

The emotional factors may vary in degree from case to case and play a more important part in one patient than in another. It can be said, however, that there is an emotional disturbance in every case of "non-specific" colitis. Unless the emotional factor is solved, medical and surgical

---

Presented at the annual meeting of the Minnesota State Medical Association, Duluth, Minnesota, June 8, 1954.

care will be greatly retarded and frequently complete cure will not be possible.

Careful investigation of the life experiences and emotional responses of patients suffering from ulcerative colitis, reveals a close relationship between the appearance of a painful psychological situation and the appearance of symptoms of the disease. The histories of these patients show that they fall into very similar categories. They show many infantile traits, among them an inability to control the bowel—a common infantile response to fear.

The ulcerative colitis personality according to Daniels,[3] is apt to be self-centered and dependent. The dependency is shown particularly toward the mother or a mother substitute, frequently an older sister. This dependency is often maintained by the involved parent or substitute, at the expense of the patient, especially through fostering illness under the guise of care. As would be expected in dependent persons, many ulcerative colitis patients are emotionally and sexually immature, and do not carry responsibility well. The Yale group called them the "giver-uppers." In this they are the opposite of the peptic ulcer patients, who are aggressive as a rule and seek responsibility. The males are inclined to be of the passive type, pathologically attached to the mothers and frequently unmarried. Of Murray's[8] original series of fifteen cases, seven were men and unmarried. The women, who are more frequently married, are apt to be of the fussy type of housewife, with a marked sense of neatness.

Wittkower[9] found that psychiatric disorders were far more frequent in the ulcerative colitis patients than in the average population. These manifestations antedated the colitis and were so gross that a special controlled group was not deemed necessary. He found no uniform personality make-up, but his cases fell into three groups, with common characteristics within the group; a fourth group consisted of the miscellaneous personality types. The first group was characterized by obsessional traits; the second, which was made up entirely of women, by hysterical traits; and the third by depressive or schizoid trends. The personalities in childhood coincided with those in adult life, except that there was often an exaggeration of characteristics after maturity.

Comparative studies by Grace, Pinsky and Wolff[6] of carefully matched groups of patients suffering from ulcerative colitis have shown that the length of illness, rate of serious complications and mortality rate were all considerably less in a group that was managed by the psychiatric approach, than in a controlled group in which the importance of the emotional factors was either not recognized or was neglected.

To theorize about the dynamics whereby psycho-biological forces result in a demonstrable organic pathology and physiological malfunction is indeed intriguing. Many hypotheses have been postulated but all leave much unanswered. Perhaps it will never fall within the scope of man to understand all about himself, either as a physical being or as a thinking and feeling organism; nevertheless, we must continue to strive to solve these problems in order to further man's welfare.

In discussing the role of the hypothalamus in relation to psychosomatic disorders, Grinker[7] states:

> "The hypothalamus developed from the basal portion of the diencephalon under the influence of the medial forebrain bundle is in a position favorable for its role as a central integrator of several important functions It receives afferent fibers from the ascending tracts by way of the thalamus and subthalamus, and sends efferent fibers which directly or indirectly affect the activity of the entire autonomic nervous system. The hypothalamus integrates individual activities of viscera, endocrine glands, and smooth muscles with reference to the economical needs of the entire organism. Such regulation and integration of the body's internal milieu serves to maintain what Cannon termed 'homeostasis.'
>
> "If the hypothalamus is an autonomic center concerned with maintaining a constant internal environment, it probably has two general systems, each with its own afferent and efferent connections and acting reciprocally to each other. There is considerable evidence that these dual centers exist. The posterior hypothalamus is an orthosympathetic and the anterior a parasympathetic center. The hypothalamus represents visceral activity in more special highly organized combinations, a regrouping from the lower levels of the nervous system from such centers as the spinal, bulbar, pontine, et cetera. Its orthosympathetic areas control and integrate all visceral activity, its parasympathetic areas are more highly specialized and discreet."

According to Fulton[5]:

> "The autonomic division of the nervous system can no longer be regarded as a purely peripheral system, but rather as an elaborately organized division of the

> central nervous system with representation at all levels. At each level, moreover, the somatic and autonomic systems dovetail with one another, and while the somatic may predominate in a given region—and thus obscure the autonomic component—it is generally impossible to evoke a somatic reflex that does not have an autonomic concomitant of central origin."

Alkan[2] first clearly stated that organic disease may be profitably studied by psychological methods. He indicated that psychogenic disturbances within the field of the autonomic nervous system may result finally in organic changes, the morphological mechanisms of which form only the last link of an intricate causal chain. He stated that spasms of smooth muscle, which secondarily lead to anemia of an organ, stasis, muscular atrophy or infection may be the expression of emotional conflicts. As a result of these secondary factors, organic changes result in the visceral tissues or somatic structures, which of themselves, as terminal events, are irreversible and constitute the so-called organic disease.

Alexander,[1] through his psychoanalytic researches, called attention to the role of psychic conflicts in the etiology of gastrointestinal disorders. He stated, however, that no disturbance of innervation of an organ could symbolically express a specific phantasy or a repressed idea. On the other hand, an organ's specific function could be used to express a tendency or psychic direction which by a process of conflict would not normally be expressed through the voluntary nervous system and its organs of expression.

Fulton[4] has stated:

> "Newer disclosures concerning the relation of the cerebral cortex to the autonomic nervous system give an adequate physiological basis for the relationship long recognized between mental states and visceral processes. To be a little more specific, it is clear that one now has adequate reason for believing that the load which is placed upon the heart and circulation may be determined in large measure by the mental status of the individual, and be thus quite independent of the more obvious factors of over-exercise and exertion. The heart and circulation may be worked just as hard, to just as much of a detriment to the body as a whole, from the swivel chair as from the rower's seat. Many disturbances of gastro-intestinal functions undoubtedly have a similar basis and one might add that instead of referring to them as "psychogenic disturbances" one may more appropriately designate them as purely physiological aberration and explicable in terms of recognized physiological mechanisms. The more precise analyses of these psychosomatic relationships will come from the study of man, and hence can come only through active collaboration between clinician and physiologist."

In anxiety, danger is not real; it is unknown, internal, and results from an increase in instinctual tension demanding expression. Freud called it a condition signal within the ego, conscious within the personality as a warning of impending danger. Anxiety produces specific unpleasurable feelings, efferent discharges and their perception. Anxiety often results in a paralysis of certain higher ego functions. It is, then, the first sign of an autonomic influence on the cortex which has been learned by previous testing to indicate danger for the organism. It is a feeling which accompanies autonomic forces sufficiently strong to overcome cortical inhibition and force the cortex into activity, movement resulting, in an attempt at solving the situation which has evoked an internal tension. The organism attempts to solve the conflict by psychological measures equivalent to fright or flight. Compromises at times are attempted. Successful solutions are frequently not possible and the cortex will allow regression and infantile modes of emotional expression for the sake of avoiding prolonged or greater emotional feeling. The result is visceral expression or organ dysfunction, that constitutes the first step toward organic disease.

Psychiatric consultation is not always necessary in the treatment of ulcerative colitis. Psychotherapy can, in many instances, be successfully carried out by the attending physician, provided he is conditioned to the patient's needs, shows a real interest in the emotional aspects of the illness and has adequate understanding of what psychotherapy entails. When one considers the personality make-up of most patients with ulcerative colitis, it becomes evident that a supportive type of treatment will usually be the most successful. A supportive approach is a necessity during the acute phases of this disease. Some therapists might argue this point and claim that supportive type of treatment weakens the patients by making them too dependent upon the physician, thus making it difficult for them to build up their own resources to a point where, upon recovery, they can again take their place in society. There is a degree of danger in supportive treatment unless it is done adeptly. There is a definite place for more direct and intensive psychiatric therapy when the patient has improved to a point where the uncovering of painful emotional experiences will not endanger a relapse of the disease.

Careful attention to the physical treatment of the patient, applied daily, with a goodly mixture of support and protection will be found to be the best treatment. During the course of therapy, the patient must be given ample opportunity to express fully his life's experiences in a longitudinal fashion, starting with his childhood experiences and on up through his school years, adolescence and college, his work adjustments, social adjustments, including marriage; in fact, an opportunity to express everything that has happened to him up to the time of the illness. The attitude of the therapist must be that of a sympathetic listener. There is no room for admonishment, lecturing or preaching to a patient of this kind. From time to time during the interview, acknowledgment of the nature and meaning of the life's experiences of the individual should be made in a fashion that shows the patient a sympathetic understanding and carefully avoids any manifestation of unfavorable or critical attitude toward the patient and the way in which he has lived.

It is well for the patient from time to time in the course of the interviews, to be reassured of his physician's attitude toward him. It is necessary to be quite emphatic at times in showing the patient that the physician desires to understand him, recognizes him as a worthy fellow and shows by word and manner, that in addition to being a medicine man, the doctor is a counselor and friend.

Since no patient lives in an isolated emotional environment, it is necessary for the physician to be thoroughly acquainted with all the contributing factors in the immediate life situation of the patient. This entails interviewing many other members of the family, especially the husband or wife. Oftentimes unpleasant relationships between immediate members of the patient's family or in-laws, have helped to create an unbearable situation for the patient, and thus contribute to his illness. In these instances every effort should be made to remove these disturbing factors. It is often necessary to exclude certain visitors, who the physician feels would be unwelcome to the patient. Isolation may be necessary and advantageous in some instances in order to avoid unfavorable reactions on the patient from incidents occurring in the immediate environment.

The nursing staff in charge of the patient should be adequately briefed relative to the particular significance of their part in the treatment program. In these days of nursing shortage and understaffing of competent, well-trained nurses, those in immediate charge of the nursing duties on a given section of the hospital are usually over-worked and since they are human, their dispositions do not always make for the best relationship with the patient. This is particularly true in a case requiring very close attention to the patient's physical needs, such as feeding, cleanliness and attention to exactness in regard to medication. Since the ulcerative colitis patient is usually emotionally ill-at-ease, he is quick to sense omissions in his care and interpret neglect as being willful, because of the particular nature of his illness. Every effort should be made to create, as far as possible, an element of smooth teamwork on the part of the attending physician and the nursing staff. Unless this is done, repeated incidents will happen during the course of the day that will largely undo what the physician is trying to accomplish.

Summary

1. The need for the consideration of emotional disturbances in the treatment of ulcerative colitis is pointed out.

2. The hypothalamus is discussed in the light of its being an integrating center for autonomic nervous function and its relation to emotional stresses is reviewed.

3. The nature of anxiety and its effect upon physiological states is described.

4. Team work in the treatment of ulcerative colitis is stressed. This team work calls for recognition and proper timing on the part of the surgeon, internist and psychiatrist in relation to their contribution to the treatment program.

Meconium Peritonitis

Report of a Case and Review of the Literature

GEORGE R. McNEAR, JR., M.D.
Mankato, Minnesota

Report of Case

The patient was a newborn infant, whose birth weight was 6 pounds 14½ ounces, and length 20 inches. The child was born spontaneously by vertex presentation after normal labor. The mother's antenatal course was uneventful.

During the following two days, temperatures were taken on the infant four times a day; the readings being as follows:

Minimum reading 97.6 at birth.

Maximum reading 97.8 at 10:00 A.M., the second day of life.

The color at all times was good, and the baby was put to breast after the usual twenty-four-hour waiting period. The infant was alert, the chest was clear, and no evidence of abnormality was noted until the morning of the second day of life, at which time the mother called the physician to her bedside and said that she thought the abdomen of the child was somewhat distended. There was no evidence at this time of any fetal distress, and the doctor who saw the baby was unable to find any physical abnormality other than a mild distention of the abdomen. The liver and spleen were both palpable and the abdomen was soft. The latter was tympanitic over much of its surface.

Approximately seven hours after the abdominal distention was initially observed, the baby was again examined, the distention previously noted had somewhat increased. The physician suspected meconium ileus had occurred and gave a 2-ounce normal saline enema, which was returned along with a small amount of inspissated meconium. The baby at that time did not seem to have respiratory distress. Because of the result of the enema, in returning inspissated meconium, another 2-ounce saline enema was given. Within a few minutes respiratory distress was evident, the respirations becoming shallow and gasping. The enema was not returned, and the infant was placed in an incubator under oxygen. It was thought, at the time, some perforation of the rectum or sigmoid colon by the enema tip might have occurred.

An x-ray was taken, and evidence of some free air was seen under the left dome of the diaphragm. The consulting surgeon was of the opinion that immediate surgery should be undertaken to close the perforation of the bowel. Further x-rays were then taken in lateral and upright postures, and more free air was evidenced in the peritoneal cavity, confirming the diagnosis of a perforated viscus. While preparing the infant for surgery she suddenly expired approximately eight and a half hours after the abdominal distention was originally observed.

Autopsy Findings

The embalmed body was that of a two-day-old infant measuring 49.5 centimeters long and weighing 3,125 grams. The abdomen was distended. There were no other external abnormalities.

The skull and central nervous system were not examined.

Heart.—The heart was normally placed, but was enlarged on the right, primarily by an enlarged right auricle. The pericardium was smooth. The sac contained no fluid. The heart chambers were opened and no abnormality other than right auricular dilatation was noted. The valves appeared competent. The foramen ovale was patent and the ductus arteriosus was open. The great vessels of the heart were normally placed and showed no abnormality.

Lungs.—Pleural spaces were smooth and free of fluid. Both lungs floated when immersed in water. Cut surfaces showed no evidence of inflammation or infection. The trachea and bronchi were unobstructed. Hilar lymph nodes appeared normal.

Abdominal Cavity.—All peritoneal surfaces were inflamed and covered by a thick, yellow-green, purulent material, and a moderate amount of foul-smelling air was present in the peritoneal cavity (Figs. 1 and 2).

No gross lesions were noted in the stomach, duodenum, jejunum, or first portion of the ileum. The distal ileum, the ascending, transverse, and upper half of the descending colon all showed a green-brown discoloration, and a moderate to marked amount of distention. The distention was particularly noted in the caecum, where an area, 2 centimeters in diameter, on the anteromedial aspect, was black and perforated in its center by a 2 millimeter defect (Figs. 3, 4, 5, 6, and 7). A considerable amount of firm, inspissated meconium was removed from the caecum.

The colon below the junction of the descending colon and the sigmoid was completely normal, and there was no evidence of perforation from the enema tip. The mucosa of the rectum and sigmoid were not damaged.

The liver was covered by a thick, green, purulent exudate. Cut surfaces showed no recognizable gross lesion. Biliary tracts were patent.

Presented at the annual meeting of the Southern Minnesota Medical Association, Winona, Minnesota, September.

Dr. McNear is with the Mankato Clinic, Mankato.

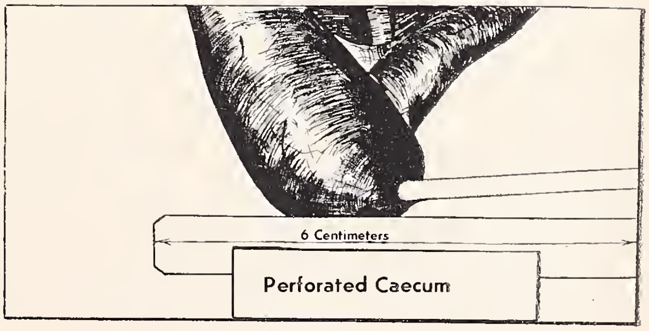
Endocrine System.—The thymus was slightly enlarged but was not constricting the trachea or compressing the vessels of the anterior mediastinum. The thyroid was not enlarged. The adrenals were normally located and did not appear enlarged. The cut surface of both adrenals showed a thinning of the cortex, with some evidence of hemorrhage into it.

Diagnosis.—The diagnosis on the basis of gross autopsy findings was: (1) Peritonitis, severe, acute, due to (2) Perforation of the caecum—cause of caecal perforation unknown, and (3) Right heart failure.

The autopsy findings were difficult to understand,



6 Centimeters
Perforated Caecum

Fig. 7

as we were unable to determine any way in which the caecum could have been perforated, and until the microscopic findings were returned, we remained in the dark.

Microscopic findings showed several things of significance. The first was hemorrhage into the adrenal cortex, and, second, gangrene around the site of perforation, apparently caused by compression of the blood vessels of the caecum by some foreign body. This finding of trophic gangrene led us to the diagnosis of meconium peritonitis.

It was felt by the pathologist who did the autopsy, that there was sufficient inspissated meconium in the lower gastrointestinal tract to account for the perforation. Therefore, the final diagnosis, based on gross and microscopic pathology, was peritonitis, due to perforation of the caecum by pressure necrosis from inspissated meconium.

Discussion

In 1838, Sir James Y. Simpson first described fetal peritonitis. At the time of the original description, twenty-five cases were discussed. Since that time several authors have broached the subject of meconium peritonitis, and occasional isolated case reports and reviews have appeared in the literature.[1]

Perhaps one of the best reviews of this condition is published in the *American Journal of Roentgenology and Radium Therapy,* by Dr. Edward B. D. Neuhauser; in this review the radiographic criteria for diagnosis are summarized and examples given. His article gives three additional cases, and all three of these showed one or more congenital anomalies of the bowel, the most common being atresia. In all of his cases one or more irregular plaques of calcification, visible on roentgenogram, were found, and these proved to be meconium, which had been extruded through a perforation and then undergone calcification. However, in no case was he able to demonstrate the site of perforation, either at operation or autopsy.[5]

According to Kneidel,[4] the first description of a case of congenital intestinal obstruction was given by Calder in 1733. Various incidences of this disease have been given; Kneidel's vary from one out of 20,000 births to one out of every 1,000 births by other authors. However, Davis and Poynter[3] indicate that of the 392 cases reported in the literature as of 1922, only 25 per cent (101 cases) occurred in the ileum and caecum. The mechanism of obstruction and perforation associated with meconium ileus has been thought to be related to fibrocystic disease of the pancreas. In this situation, the peristaltic waves passing through the intestine are apparently unable to force the thickened meconium through the lumen of the gut, and obstruction results.

It was pointed out by Neuhauser and Kneidel that the majority of cases of meconium ileus associated with obstruction or perforation were usually the result of one or another congenital lesion of the intestinal tract, associated with faulty development. Pyloric stenosis; ileal and jejunal atresia; diaphragmatic hernia causing gastric obstruction; imperforate anus; duodenal stenosis and/or atresia, were the commonest types of congenital anomalies noted.

In our case, no evidence of congenital malformation of the gastro-intestinal tract was seen. In addition, we were able to demonstrate the exact location of the point of intestinal perforation. Microscopically, we were able to see evidence indicating pressure necrosis from the inspissated meconium. We were not able, however, to find the classical radiological picture of meconium peritonitis, *viz:*

1. One or more irregular plaques of calcification visible in the peritoneal cavity, either lying within the bowel lumen, wall, or parietes.
2. Markedly dilated loops of small bowel with numerous air and fluid levels.

On the other hand, our case did demonstrate the classical x-ray findings of perforation of a hollow viscus, clearly demonstrating air beneath the diaphragm and beneath the abdominal wall.

Because of the failure of the autopsy to demonstrate calcification of the meconium spilled within the peritoneal cavity, it is our conclusion that the perforation must have been quite recent in its origin.

It has been pointed out[2] that it is possible for rupture of the bowel to occur any time after the fifth month of gestation, and that meconium can be spilled any time after perforation occurs. In the fifth month, intestinal peristalsis seems to start and prior to that time the gastro-intestinal tract is silent. Had rupture occurred very long prior to the death of our infant, some evidence of calcification, or fibrotic walling-off of the foreign body, would have been evidenced at autopsy. However, we found only thick, purulent meconium covering the peritoneal surfaces of the abdominal cavity, without any evidence,

Medical Partnerships

RONALD S. HAZEL
Saint Paul, Minnesota

THERE appears to be a growing interest among physicians and surgeons, both in the field of general practice and in the various specialties, in combining the tangible and intangible resources of two or more doctors for practice as a group or firm. Since the medical profession in common with other professions is generally prohibited from practicing in or through a corporate body, the partnership form of organization seems to be the only practical means of combining resources. For that reason an article touching upon the various problems inherent in a partnership organization and some of the solutions of such problems seems timely.

It is perhaps only natural that most professional and businessmen contemplating the formation of a partnership (and it nearly always involves the combining of the resources and efforts of persons who are good friends, as well as persons with common professional or business interests), think only of three or four matters to be decided at the outset. The questions which occur to them immediately are: What shall we call our firm? What will be our office or business location? How much property by way of cash and equipment will each prospective partner contribute? How will we share in the profits? Strangely enough, there is almost never any thought of losses or future misunderstandings or disputes.

The legal profession has long since learned that misfortunes, misunderstandings and disputes will arise in some partnerships. Not only that, but sooner or later every partnership is going to be terminated with accompanying problems incident to the business aspects of dissolution. For that reason, lawyers generally urge prospective partners to devote great care and thought to their partnership agreement and to reduce it to writing for future certainty.

When Doctor "Jim" and Doctor "Joe" decide that they would like to form a partnership and pool their combined equipment, knowledge, experience and other resources, they should immediately make up their minds that they are undertaking a business relationship, the details of which should be worked out in advance so far as possible. They should sit down and lay aside the sensitivity that so frequently affects discussions between close friends and discuss all the aspects with complete candor.

Their discussions should include among others, the following problems:

1. The firm name under which the partnership will operate and its office location.
2. The date when the partnership shall commence and the term for which it shall continue (usually from year to year until such time as it is terminated as provided in the agreement).
3. The original acquisition of supplies, fixtures and equipment and the repair, maintenance and replacement during the life of the partnership.
4. The definition of just what receipts from particular sources of income shall constitute partnership property.
5. The definition of partnership expenses to be paid out of funds of the partnership.
6. Whether automobiles shall be purchased by the partnership or supplied by the individual partners, and the manner of obtaining and paying for liability and property damage insurance necessary to protect the partnership as distinguished from the individual.
7. The bank in which the partnership bank account shall be established and the responsibilities of the partners with respect to that account.
8. Nature and extent of the records (including books of account) to be kept by the partnership, the place of keeping such books and the rights of each partner with respect to access to all records.
9. Whether or not the firm's books of accounts are to be supervised or checked by in-

---

Mr. Hazel is a practicing attorney at law in Saint Paul.

dependent auditors; if so, how often and whether the independent audit report shall become conclusive as to each of the partners within some definite period after it is received.

10. Manner and times of distribution of net income.

11. Times and amount of current drawings by each partner from current income for living and other personal expenses.

12. Manner of termination of the partnership and the methods of liquidation of assets upon dissolution.

13. Treatment of accounts receivable owned by the individuals at the time the partnership is formed.

14. Restrictions, if any, upon each partner as concerns his activities outside the partnership.

15. Amount of vacation time or other free time to be allowed to each partner during the existence of the partnership.

16. The fixing of responsibility, if so desired, for particular types of practice, for example, obstetrics.

17. Any restrictions which are to be placed upon any partner with respect to his practice in the event of termination of the partnership.

The possible solutions to most of the questions or problems enumerated are quite obvious, and will not be the subject of further comment here. However, several of the matters which should be covered in every good partnership agreement seem worthy of brief comment.

Quite frequently medical partnerships comprise an older doctor who owns substantial equipment and controls a substantial practice, and a young doctor whose resources in that respect are small or almost nonexistent. In that situation the supplies, fixtures and equipment with which the partnership will start operation may be furnished by the older doctor either on the basis of an appraised or an agreed value, a prescribed percentage of which the younger man is to pay to the older partner out of future earnings, or the older doctor may contribute these supplies to the partnership with no provision for reimbursement but only a provision that upon termination of the partnership any of the original supplies, fixtures and equipment still in use shall revert to him. Where the physicians or surgeons forming the partnership are on a more equal footing, it is possible that each will have substantial holdings of supplies, fixtures and equipment to contribute, in which event the value can be appraised or agreed upon and any differential adjusted by cash contribution to the partnership account, or such difference in value can be taken into account in the fixing of participation by each partner in profits and losses. In any event, the agreement should further specify the manner of procuring and paying for repairs and maintenance and replacement equipment.

Meticulous care should be exercised in working out the terms of the agreement for distribution of net income (and in the case of misfortune, the sharing of losses) so that each partner will know from time to time exactly where he stands with reference to partnership earnings. In most instances, the partners do not start on an equal footing, and it is intended that the younger partner with less experience and less to offer the partnership participate in earnings (and share in costs and losses) on a basis which starts with a relatively small proportion and increases from year to year until he arrives at a point where his participation is perhaps equal to that of any other partner. It is highly desirable that the partnership agreement set forth precisely the participation of each partner from year to year and that subsequent years not be left to future agreement. If, in years following the commencement of the partnership, it becomes obvious that the provisions respecting distribution of income as originally set forth are inequitable, the agreement can always be amended to express any new arrangement.

An audit of the partnership accounts by an outside firm of accountants may seem like a small matter, but to those of us who have had extensive experience with business and professional firms, it is perhaps one of the most important items for consideration. If the audit is done by competent people, it can serve several purposes. In the first place, the auditor will consider and report any improvements which can be made in the practices of the firm's bookkeeper to make the accounting more efficient and informative. Secondly, the audit should disclose not only inefficiency, if any, in the handling of the business practices of the partnership, but also any possible dishonesty on the part of employes—a problem which exists somewhat more frequently than most persons are aware. In the third place, the audit, if made annually, and the report from the auditor informs each partner as to just what progress the partnership is making and avoids possible necessity for going back over a number of years to settle a dispute as to individual income received from the partnership or costs paid by the partnership and allocated to the individual partners. In the fourth place, the audit is the best possible supporting data for necessary income tax returns of the individual partners, insofar as those returns reflect income and deductions allocable to partnership operations.

It is desirable that the partnership agreement cover the question of termination (a) by notice given by a disgruntled partner a specific length of time before the end of a fiscal year, calendar year or month, (b) by entry into the military service and remaining in such service for a prescribed period of time and (c) by retirement of a partner. The death of a partner, of course, terminates a partnership as a matter of law. Equally important is a provision in the partnership agreement covering liquidation of assets upon dissolution. In the absence of some agreement all partnership assets would be subject to liquidation and the receipts therefrom would be distributed in the proportion of the partners' ownership of the assets and participation in income. Quite obviously this could result in a substantial loss and it is perfectly feasible to provide in the partnership agreement that upon termination the assets of the partnership shall be distributed in a particular manner. For instance, it may be provided that a particular partner shall take all or a specified portion of the equipment and fixtures and the office location. Likewise, it may be provided that the accounts receivable will be liquidated in a particular manner. Specific provisions may be inserted for liquidation in one fashion if the partnership is terminated by notice for military service and in another manner in the case of the death or retirement of a particular partner.

In those instances where a doctor with an established practice forms a partnership with a younger and to some extent untried man, it is particularly important to consider and agree upon any restriction upon the practice of one or another of the partners in the event of termination of the partnership. It is generally considered to be a valid provision provided that the restriction applies only to a reasonable area and extends only for a reasonable time. There would seem to be little doubt that a partnership agreement between two doctors practicing in a town of modest size might well provide that in the event of termination of the partnership, the younger man would be prohibited from practicing in that town or its immediate environs for a period of one, two or possibly three years.

In this article no attempt has been made to touch upon income tax or other tax aspects of the partnership. As a matter of fact, a partnership is not recognized as a legal entity in the same sense that a corporation is so recognized and no separate income tax is imposed upon it unless it elects to be subjected to a corporate income tax under the 1954 Revenue Code. The partnership as such makes an information return disclosing partnership income and partnership expense as well as the net distribution to the partners. The partnership operation does not, therefore, have the effect of imposing a double tax upon the income ultimately realized by the individual partners.

ACH

ACHROMYCIN has proved effective against:

Pharyngitis
Acute Bronchitis
Tonsillitis
Pertussis
Otitis Media
Scarlet Fever
Osteomyelitis
Epidermal Abscesses
Acute Brucellosis
Pancreatic Fibrosis
Typhus Fever
Sinusitis
Gonorrhea
Bacillary Dysentery
Pneumonia with or without Bacteremia
Bronchopulmonary Infection
Acute Pyelonephritis
Chronic Pyelonephritis
Mixed Bacterial Infections
Soft Tissue Infections
Staphylococcal Septicemia
Pneumonoccal Septicemia
Urogenital Tract Infections
Acute Extraintestinal Amebic Infections
Intestinal Amebic Infections
Subacute Bacterial Endocarditis

ROMYCIN*

HYDROCHLORIDE
Tetracycline HCl *Lederle*

A TRULY BROAD-SPECTRUM ANTIBIOTIC

Clinical research has proved ACHROMYCIN to be effective against more than a score of different infections, including those caused by Gram-positive and Gram-negative bacteria, rickettsia, certain viruses and protozoa.

In addition to its true broad-spectrum activity, ACHROMYCIN provides more rapid diffusion than certain other antibiotics, prompt control of infection, and the distinct advantage of being well tolerated by most persons, young and old alike.

ACHROMYCIN, in its many forms, was accepted by the medical profession in an amazingly short time. Each day more and more prescriptions for ACHROMYCIN are being written when a broad-spectrum antibiotic is indicated.

Serological Testing for Syphilis in Minnesota

A Recommendation for a More Productive Use of Routine Testing

ANNE C. KIMBALL, HENRY BAUER, AND R. N. BARR
Minneapolis, Minnesota

MINNESOTA has experienced a marked reduction in cases of syphilis since 1946, when 1,844 cases were reported. In 1953 only 327 cases were reported. During this period there has been no appreciable reduction in the number of specimens submitted to the Minnesota Department of Health Laboratories for serological tests for syphilis. These factors led the Division of Medical Laboratories to evaluate its serological testing program to determine how serological testing can best be used as a case finding tool.

TABLE I. COMPARISON OF ENTIRE YEAR AND 4.4 PER CENT SAMPLE

	Entire Year		4.4% Sample	
	No.	%	No.	%
Kline Test Result				
Negative	262,195	95.18	11,550	95.19
Doubtful ± or 1+	5,551	2.02	241	1.98
Positive 2+, 3+ or 4+	7,717	2.80	343	2.83
	275,463	100.00	12,134	100.00
Number of Tests				
Screen test only	254,201	92.28	11,217	92.44
Three tests	17,667	6.41	785	6.47
Five tests	3,595	1.31	132	1.09
	275,463	100.00	12,134	100.00
Overall Testing Result				
Kline or VDRL & Kolmer negative	266,968	96.92	11,762	96.93
VDRL positive & Kolmer positive 3+ or 4+	4,217	1.55	196	1.45
Other combinations of VDRL & Kolmer test results	4,278	1.53	176	1.62
	275,463	100.00	12,134	100.00

A comparative study was made of blood specimens submitted and reported cases of syphilis. To determine from whom specimens were collected, by whom submitted, and for what reasons, data were studied with reference to such factors as age, sex, marital status, whites and non-whites. Findings from the specimen study were correlated with similar data from reported cases. When appropriate, data were compared with the total Minnesota population, using 1950 census figures.[2,3]

Method

Source of the Data.—The study was based on a 4.4 per cent sample of all blood specimens tested in 1952 in the health department laboratories and on all reported cases in which the diagnostic serology was done in the department laboratories. The year 1952 was selected for study as the most recent year available.

A total of 278,357 blood specimens was received in 1952. This included 2,496 (0.9 per cent) untested specimens, which were unsatisfactory due to insufficient serum or hemolysis, and 398 specimens for which the results were not reported because the patient and/or physician were not identified on the data card and could not be subsequently identified. The sample was drawn from the remaining 275,463 specimens which were tested and on which results were reported.

The sample of 12,134 (4.4 per cent) was selected by an appropriate random sampling method to provide a statistically satisfactory representation of the total group of 275,463. The close agreement between the entire year and the 4.4 per cent sample shown in nine comparisons in Table I indicates that the sample error in this study was small. The distribution of the sample in successive thousands of the numerical specimen number series was within expected theoret-

---

From the Minnesota Department of Health.

ical sampling limits to give further assurance that the sample error was small.

There were 479 new cases reported in 1952; 104 cases (21.7 per cent) were eliminated from the study because the diagnostic serology was done in laboratories other than those of the Minnesota Department of Health. The study included all of the remaining 375 cases. Age, sex, marital status, color, and patient residence on cases were correlated under similar data from the specimen sample.

TABLE II. AGE DISTRIBUTION

10,674 Specimens in Sample—372 Reported Cases of Syphilis*

	1950 Minnesota Population %	Specimens in Sample %	Percentage of Total Population Tested %	Cases Reported %	Specimens Tested Per Case Found No.
Age 0- 4	11.1	0.9	0.6	0.8	671
5- 9	9.0	0.6	0.5	0.0	—
10-14	7.5	1.0	1.0	0.0	—
15-19	7.0	9.7	11.4	4.6	1382
20-24	7.2	16.5	18.7	8.9	1210
25-29	7.4	14.5	15.9	7.8	1212
30-34	7.1	12.5	14.3	4.0	2027
35-39	6.9	9.8	11.5	3.5	1823
40-44	6.4	7.7	9.9	6.5	779
45-49	5.9	6.3	8.7	9.9	414
50-54	5.7	5.5	7.8	11.0	324

65-69	3.5	3.0	6.9	10.8	182
70-74	2.5	1.8	5.9	5.7	209
75+	3.0	1.9	5.2	4.8	261
All Ages	100.0	100.0	8.1	100.0	651

*Age not given on 1460 specimen data cards (12.0%) and on three case report cards (0.8%).

Reported case data came from two sources, case report cards and the data card accompanying the first specimen submitted for laboratory diagnosis. Specimen data came from specimen cards.

Limitations of the Data.—Accuracy of specific data (age, marital status, diagnosis, etc.) for each individual tested and each reported case was limited by the accuracy of the information given on the cards submitted and by the fact that many cards were incomplete.

The specimens tested cannot be considered as representative of the same number of persons because of repeated testings on some individuals and there was no way to determine accurately the amount of repeat testing. For all calculations of the percentage of population tested there has been a correction introduced to allow for repeat testing. In each table, the number on which there was no information in the sample (10 to 15 per cent) is used to represent the extent of repeat testing. It is probable that 10 to 15 per cent is an overcorrection.

Results

Geographic distribution of the testing by patient residence varied from less than two per cent of the population tested in some counties to more than 13 per cent in others.* Variation in testing did not correlate with density of population nor with the number of physicians per 1,000 of population in each county.

In the seventeen counties where less than two per cent of the population was tested, 3.1 reported cases of syphilis were found in 1952 per 100,000 persons. In nine counties where more than 10 per cent of the population was tested, the case rate was 10.7. This increase from 3.1 to 10.7 in cases found with increase in percentage of population tested is not a smooth progressive increase. A correlation study was made of the two variables (per cent of population tested and case rate) using the 87 counties and three large cities. The correlation coefficient was 0.48. It indicates that increasing the percentage of population tested was not accompanied by a proportionate increase in the number of cases found.

Age distribution in five year age groups is shown in Table II. The table excludes 1,460 specimens (12.0 per cent) and three cases (0.8 per cent), because patient age was not given.

---

*Counties with more than 13 per cent of the population tested were Itasca, St. Louis, and Koochiching where employe testing is routine for some industries in those areas; but since the specimens were submitted by private physicians and carried no indications to distinguish the employe examination from the usual private practice specimens, this testing was not included in the industrial group shown in Table VIII.

*Age, color, or age and color not given on 1792 (14.8%) specimen cards. Age not given on three case report cards.

Very little blood testing was done and only three cases of syphilis (0.8 per cent) were found in persons from birth to fourteen years of age. The largest amount of blood testing (43.5 per cent) was done in the three age groups twenty to thirty-four years, inclusive. From 14.3 to 18.7 per cent of the Minnesota population was tested in these three groups but they accounted for only 20.7 per cent of syphilis found. Most of the cases reported (54.0 per cent) came from persons aged fifty or above. The number of specimens tested per case found showed a marked change at age forty. Below age forty, 1,440 specimens (weighted average) were tested per case found; above age forty, there were 320 specimens (weighted average) tested per case found; in the age group sixty-five to sixty-nine years there were 182 specimens tested per case found.

Distribution by age and sex in the white and non-white groups is shown in Table III, with age distribution shown in four large age groups, birth to fourteen years, fifteen to thirty-four, thirty-five to fifty-four, and fifty-five and older. The table excludes the 1,792 specimens (14.8 per cent) and the three cases for whom data were not available. The population in Minnesota is 99.0 per cent white,[2,3] and 97.7 per cent of the testing was on this group. Whites accounted for 82.5 per cent of syphilis found. The state population of non-whites is 1.0 per cent,[2,3] and 2.3 per cent of the testing was done on this group. Non-whites accounted for 17.5 per cent of the syphilis reported.

The yield of reported cases in non-whites was one case per 82 specimens, as compared to one case per 747 specimens in whites. In both the whites and non-whites, the heaviest testing of the population was in the fifteen to thirty-four year age groups. They were the only age groups in which there was significantly more testing of females than males, with routine pregnancy examinations accounting for this increase. Of the non-white female population age fifty-five and above, 3.8 per cent were tested, with no cases found.

Table IV shows the various types of syphilis reported by age groups in the white and non-white groups. Primary and secondary syphilis were found largely in young adults; twenty-six of the thirty-seven cases were found in the age group fifteen to twenty-nine years. The asymptomatic types, including early latent, late latent, and asymptomatic central nervous system syphilis, were found in adults of all ages but predominantly above the age of forty. Congenital syphilis was reported in all age groups, but nine of the 18 cases were found in the fifteen to twenty-nine-year-old group. In the white group, 77.7 per cent of the cases were found in persons over age forty, and in the non-white group 33.3 per cent of the cases were found over age forty. Of the total cases in whites, 7.7 per cent were infectious; 20.0 per cent of all cases in non-whites were infectious.

Table V presents the distribution with reference to marital status. It excludes a total of 1,470 specimens, including 259 children and 1,211 (10.2 per cent) adults where marital status was not known, and three cases of congenital syphilis in children aged birth to four. The sample indicates

*1470 specimens eliminated: 259 from children and 1211 (10%) with marital status not given. Three cases eliminated: age 0-4.

that 7.8 per cent of widowed and divorced males and 6.8 per cent of widowed and divorced females were tested; 10.5 per cent and 10.2 per cent of cases were found in these males and females, respectively. A new case was found by testing 125 specimens from widowed and divorced males and 244 specimens from widowed and divorced females.

Table VI shows the reason specimens were submitted and the number of cases reported. One-half per cent of the specimens were submitted for "Following Progress of Anti-luetic Treatment." Six cases of syphilis were found in this group.*

Only 0.6 per cent of the specimens indicated "Suspected Case of Syphilis"; fifty-five cases were found in this group. This was the most productive group tested with twenty-eight specimens tested per case found. The fifty-five cases provided 59.5 per cent (22) of the total number of thirty-seven cases of infectious syphilis, with fourteen primary and eight secondary.

Routine pregnancy examinations constituted 11.9 per cent of the testing, with a total of 32,915 specimens. (The sample represents an estimated 33 per cent of all pregnancies, based on a total of 80,380 live and still births resulting from an estimated 100,000 pregnancies.) Only eleven cases of syphilis were found by routine pregnancy examinations, to give a ratio of 2,992 specimens per case found. Of these eleven cases, two were infectious, seven asymptomatic, and two congenital.

"Routine in General Physical Examination" was the reason marked on 57.4 per cent of the specimen cards. This included a large proportion of specimens from hospital patients and therefore does not indicate that all these specimens were from well persons. The groups for which there was "No Reason Marked" constituted 29.6 per cent of the specimens. These two heterogeneous

---

*Ideally one would not expect to find this reason on any first specimen prior to diagnosis. Possible explanations of this small bizarre group are: (1) the card was so marked by mistake, (2) the physician treated the case prior to testing, or (3) a test was done prior to diagnosis in other laboratories but was not included in the record of the case on file.

*Includes an unidentifiable number of specimens from "employment" examinations.

**Public clinics, penal institutions, blood donor centers.

†324 specimens tested per case found can be changed to 3338 if we consider the screen testing of specimens done at the two large donor centers prior to sending selected specimens to the state laboratories.

groups accounted for 87.0 per cent of the specimens and 80.8 per cent of cases (303). All types of syphilis were found in these groups.

Table VII presents the data by the source of the specimen. Private physicians provided 53.5 per cent of the specimens tested; 47.5 per cent of all reported cases; and 64.9 per cent (24) of the thirty-seven infectious cases. Specimens tested per case found was 828.

Specimens from hospitals made up 24.7 per cent of the sample; 37.9 per cent of the reported cases; and 27.0 per cent of the infectious cases. Specimens tested per case found was 483.

Specimens submitted by physicians examining for industry or corporations made up 14.7 per cent of the testing and 6.1 per cent of the reported cases. Specimens tested per case found was 1,757.

Specimens from colleges made up 3.7 per cent of the sample and 0.8 per cent of the reported cases. Specimens tested per case found was 3,396. Two of the three cases were college employes. Specimens tested per case found among college students was about one in 10,000.

In regard to the types of syphilis, half of the eighty cases of late active syphilis were found in hospitalized patients, with twenty-four central nervous system, fifteen cardiovascular and one syphilitic cirrhosis. Syphilis cases found by testing specimens from industry, corporations, and colleges were largely of the asymptomatic types.

Because of the low case yield, the pregnancy group and specimens submitted by physicians examining for industry or corporations were further analyzed as to age, previous specimen information, and white and non-white distribution as shown in Table VIII.

In pregnancy testing, more cases were found in the fifteen to twenty-four-year-old group than in any other age group, with 1,646 specimens tested per case found. Above this age, only three cases were found, with 5,448 specimens (weighted average) tested per case found. On 30.7 per cent no previous test had been done; eight of the eleven cases were found in this group. A previous specimen had been tested on 10.1 per cent of the total group; no cases were found in this group. On 59.2 per cent of the sample, no information was given as to a previous test and three cases were found in this group. A marked difference was noted between the white and non-white groups; 6,315 specimens were tested per case found in the white group and only ninety-five specimens per case found in the non-white.

Study of the specimens from physicians examining for industry or corporations revealed that the least productive age group was fifteen to twenty-four years, with 4,938 specimens tested per case found. Progressively fewer specimens were tested per case found in older persons; in the fifty-five to sixty-four year old group, 322 specimens were tested per case found. Only 1.7 per cent indicated that a previous specimen had been tested; no cases were found in this group. A comparison of white and non-white groups reveals that 3,269 specimens were tested per case found in the white group and seventy-eight specimens tested per case found in non-whites.

Discussion

The marked reduction in the number of reported cases of syphilis in Minnesota suggests that the situation is well enough in hand at the present time to consider the possibility of making more selective use of serological testing, with effort directed toward those groups which are most productive in terms of case yield.

Indiscriminate Routine Testing.—Routine testing of many population groups, including persons applying for marriage licenses,* food handlers, applicants for employment, and all hospital admissions has been recommended[5] but it has not been a procedure that is applicable in Minnesota where syphilis is as well under control as it is. If all of these groups were routinely tested, it would involve an estimated total of one million specimens a year, or the equivalent of one-third of the total population, with much unnecessary and expensive repeat testing of non-syphilitic persons.

Aspects of this study relating to geographic distribution of testing by patient residence indicated that increasing the percentage of population tested does not show a proportionate increase in the number of cases found. A better procedure appears to be to limit routine testing to groups in which syphilis is more often found and to emphasize the need for a high level of suspicion of syphilis on the part of the physician in selecting other persons for testing. Data presented in this study may assist in that selection.

Limited Routine Testing.—In this study, the groups in which syphilis was frequently found were: suspected cases, widowed and divorced persons, non-whites, and whites over age forty. Specimens from the above groups comprised 40 per cent of the specimen load, and 331 or 88.3 per cent of the syphilis case load.

The yield of reported cases in suspected cases was one case per twenty-eight specimens tested; for widowed and divorced persons, one case per 184 specimens; for non-whites, one case per eighty-two specimens; for persons over age forty, one case per 320 specimens.

With reference to marital status, widowed and divorced adults represent the smallest population group in the state. The extent to which specimens were submitted represents an even smaller percentage of the blood testing done. (Table V). However, these groups, both male and female, made up 20.7 per cent of cases found. It appears that this group is not being tested to the extent that other marital groups are tested, but it is yielding more than its proportionate share of cases. The fact that 5.8 per cent of the testing revealed 20.7 per cent of the cases suggests the need for greater testing in this group.

Another group in which there appears to be inadequate testing is the non-white female population aged 55 and over where only 3.8 per cent were tested (Table III). The fact that no cases were found in this age group would seem to indicate not so much that there was less syphilis in this group but that there was inadequate testing of these women.

Only 7.6 per cent (weighted average) of the population over 40 years of age is being tested at the present time, but all data indicated that age

---

*Premarital testing is a legal requirement in many states. At the present time, approximately one per cent of all specimens examined by the Minnesota Department of Health are to meet the premarital requirements of other states. It is estimated that the cost of processing a premarital specimen is from four to five times greater than the cost for processing the average specimen.

was a significant factor. The number of specimens tested per case found showed a marked change at age forty. (Table II). The same trend was found in specimens examined from industry or corporations (Table VIII), in which progressively fewer specimens were tested per case found in older persons. Only 34.5 per cent of the testing is from persons above the age of forty but 262 (70.4 per cent) of the 375 cases of syphilis were found in this group (Table IV).

Selected Testing.—Syphilis was not frequently found by routine pregnancy examinations; a total of 2,992 specimens were tested per case found (Table VI). Table VIII shows that few cases were found in the older pregnant women, no cases were found in the previously tested women, and few cases were found in the white group. Data available on routine pregnancy examination did not reveal which pregnancies were primipara and which were multipara, but it seems reasonable to presume that the majority of pregnant women being tested a second time were tested in a previous pregnancy.

With reference to reasons for submitting specimens, Table VI shows that the most productive group tested was "Suspected Case of Syphilis." This group provided 14.7 per cent of all cases and 59.5 per cent of the cases of infectious syphilis. In twenty-two of the thirty-seven primary and secondary cases, syphilis was suspected prior to the first blood test. Of the remaining fifteen infectious cases (40.5 per cent), seven would have been found by the suggested limited routine testing. Only eight would have been missed.

Any reduction in serological testing would be unwise from the point of view of the infected individual or from that of public health if primary or secondary cases were missed. With these cases, the lesions, symptoms, history of exposure, and darkfield examination carry more diagnostic weight than the blood test, which is primarily confirmatory. If a detailed history and physical examination did not reveal findings suggestive of syphilis and the suspicion of the disease was aroused only after the positive blood report was received, then we must continue to encourage widespread blood testing, even though it means testing several thousand bloods to find each case. On the other hand, if the suspicion of syphilis preceded the blood testing but was not so indicated on the card, we need not rely on routine testing to find 40.5 per cent of the cases of infectious syphilis, but on selection by the examining physician.

On only 1,521 specimens was the data card checked "suspected case" indicating syphilis was considered prior to drawing the specimen. Since syphilis is a protean disease, should it not be considered or suspected in taking a history or doing a physical especially in the ages over forty, rather than casually checking the data card "routine exam"?

The types of syphilis most dependent on serological testing for diagnosis are early latent, late latent, and asymptomatic central nervous system syphilis. During recent years, newly diagnosed cases of syphilis in Minnesota consist very largely of these types. In this study, 240 (64.0 per cent) of the 375 cases were of these asymptomatic types. Table IV shows that these types were found in adults of all ages, but most of them were aged forty and over. Only 34.5 per cent of the testing was from persons above the age of forty but 177 (73.8 per cent) of the 240 cases of asymptomatic syphilis were found in this group. Finding these cases is of great importance to the individual, since the disability of late active syphilis can often be prevented. Prevention of early death or permanent disability from cardiovascular or central nervous system syphilis has very tangible public benefit.*

In a sense, the eighty cases of late active syphilis in the total group of 375 cases may be considered public health failures since they were not found when the disease was in its infectious or asymptomatic state. In the same sense, congenital syphilis cases are also public health failures.

Although a single case of either does represent a public health failure, a low case rate for late active and congenital syphilis is a measure of the effectiveness of the syphilis control program not only for the present time, but also for the last ten or twenty years. It is encouraging to note the continued reduction in the failure rate (late active and congenital syphilis per 100,000) since 1940 when the failure rate was thirty-two. In 1947 the rate had fallen to 10.2. In 1952, the rate was only 3.5. These rates indicate that for more than a decade most cases of syphilis have been found in time to prevent late active syphilis and congenital syphilis. We can look forward to an even smaller proportion of such cases in the future if we can continue to find and treat infectious and asymptomatic cases.

Death certificates provide additional evidence of the completeness of coverage of the syphilis control program, with a trend toward more complete coverage strongly indicated. As recently as 1947, syphilis was the major or contributory cause of death on 135 death certificates, but of this group, only forty-four cases were unknown previous to the time of death, as checked against the Minnesota record of reported cases. In 1953, with eighty-four deaths in which syphilis was indicated as the major or contributory factor, only sixteen cases were unknown prior to death.

One of the reasons for the success of the syphilis control program in Minnesota is the excellent co-operation of physicians in private practice over a period of many years. The State Board of Health has always taken the position that a realistic approach to the control of all communicable disease, including syphilis, is to keep diagnosis and treatment in the hands of private physicians to the extent possible. With reference to syphilis, this has been the active policy of Dr. H. G. Irvine, administrator of the program since it was initiated in 1918. Data in this study reveals the effectiveness of this policy. Table 7 indicates that private physicians provided 53.5 per cent of the specimens tested; 47.5 per cent of all reported cases; and 64.9 per cent of the infectious cases. Hospitals made up 24.7 per cent of the sample; 37.9 per cent of the reported cases; and 27 per cent of the infectious cases. In combination, these two sources provided 78.2 per cent of specimens tested; 85.4 per cent of all reported cases; and 91.9 per cent of all infectious cases. Because many cases found in hospital patients and industrial examinations are later diagnosed and treated by private physicians, more than 70 per cent of actual case reports were from physicians in private practice.† The excellent record of most private physicians in case finding carries over into follow-up on source and contacts, and physician co-operation in this phase of the work continues to be invaluable to this department in its epidemiological work.

---

*This is particularly true of general paresis which if not prevented may cost the public as high as $11,000 for the institutional care of an average case. From January 1, 1951, to May 1, 1954, 74 people died in state mental hospitals with syphilis as a cause or contributory cause of death. These people spent an average of 10.3 years in the state hospitals. The annual cost of care for one year in these institutions is $1,051 (weighted average for eight hospitals).[1]

†Minnesota physicians may be interested in knowing that this is not the usual ratio. For the fiscal year of 1953, case reports of syphilis from private physicians in the United States exceeded 70 per cent of the total case reports in only nine states; these nine states included Minnesota and only two other states with populations exceeding two million.[4]

Conclusions

Selection of persons to be serologically tested for syphilis can be improved. Most of the blood testing in this study was in the age groups twenty to thirty-four, with these groups accounting for 43.5 per cent of the blood testing but only 20.7 per cent of the cases. Most of the cases were found in the age groups forty and over, and in this study these persons accounted for 70.4 per cent of the cases. Testing in those groups in which syphilis was more frequently found (suspected cases, widowed and divorced, non-whites, and whites over age forty) accounted for 40 per cent of the specimen load and 88.3 per cent of the case load. It would seem that there is need to test a greater percentage of the population in those groups where more cases are found.

Recommendations

1. Indiscriminate routine testing should be discouraged, but routine testing of selected groups is strongly recommended.

2. It is urged that routine testing be increased in those groups in which syphilis was more frequently found (suspected cases, widowed and divorced persons, non-whites, and persons over age forty). It is recognized that repeat testing following a negative in the older age groups will usually be a relatively non-productive procedure.

3. Because of the complexities of syphilis in pregnancy it is advisable to continue to recommend routine prenatal testing in spite of the low case yield. The limited data indicated that pregnant women having had a previously negative test were still negative. A more comprehensive study of this group may give criteria to guide selective testing of pregnant women.

4. The physician should suspect syphilis at the slightest provocation. When clinically demonstrable syphilis is seen less frequently a higher level of awareness is required if early cases are not to be overlooked.

5. Continuing studies of this kind will aid all persons with a concern for the effective control of syphilis in focusing their efforts on those segments of the population in which more cases are found. Future studies can be improved by:

(a) A redesigned data card which will give more accurate and complete information.

(b) Co-operation of physicians in supplying all information requested on specimen and case report cards.

Acknowledgment

The authors are indebted to Dr. J. Bearman, Biostatistician, University of Minnesota School of Public Health, for advice on sample size, and selection, and to the Division of Biostatistics for the correlation studies that were a part of this research.

SPECIALIZATION?

"When a workman is unceasingly and exclusively engaged in the fabrication of one thing, he ultimately does his work with singular dexterity; but at the same time he loses the general faculty of applying his mind to the direction of the work. He every day becomes more adroit and less industrious; so that it may be said of him that in proportion as the workman improves, the man is degraded.

What can be expected of a man who has spent twenty years of his life making heads for pins? And to what can that mighty human intelligence which has so often stirred the world be applied in him except it be to investigate the best method of making pins' heads? When a workman has spent a considerable portion of his existence in this manner, his thoughts are forever set upon the object of his daily toil; . . . he no longer belongs to himself, but to the calling he has chosen . . ."—de Tocqueville's *Democracy in America*.

Suffocation, A Killer of Children

ELDON BERGLUND, M.D.
Minneapolis, Minnesota

THIS article is one of a series on accidents and accidental deaths in children. The purpose is to inform the readers of MINNESOTA MEDICNE of the nature and magnitude of accidents in children and to encourage the development of "accident prophylactic-minded" doctors. I have been asked to discuss under the heading of suffocation the particular problems of crib deaths, hangings and ice-box deaths.

The wide publicity given to deaths of children in iceboxes has had a good effect. In many communities, laws have been made to prevent the abandonment of iceboxes in places where children can get at them. Clubs and groups have volunteered to dispose of old iceboxes. The doctor is in a good position to see that his community is free of the icebox menace. Minnesota has been free of icebox deaths so far. Similar type accidents, with suffocation occurring in cedar chests or closets, have happened in Minnesota.

Hanging deaths in children seem to fall into categories of bizarre accidents or suicides. The accidents are sometimes too realistic re-enactments of cowboy stories and the like. Children should be taught that ropes, like fire, can be dangerous. Suicide is occasionally a spur of the moment act of a hurt or angry child; more often there will be other evidences of psychiatric disturbance. Do not ignore the threats of a child who talks of suicide! He may fool you, and himself.

In 1952, twenty-seven infant deaths in Minnesota were attributed to suffocation in the crib. In only three instances were autopsies done. Evidence obtainable from other states where autopsies are done routinely would indicate that most of Minnesota's twenty-seven deaths were not due to suffocation. Werne and Garrow[3] from the office of the Chief Medical Examiner of the City of New York, reported on a series of 299 sudden deaths in infants under one year of age over a period of twenty years in one borough of the City of New York. These authors, probably more than anybody else, helped to clarify the causes of death in such instances. For many years, most of such deaths were believed to be caused by suffocation, aspiration, or an enlarged thymus. Nobody in authority any longer supports the concept of "status thymolymphaticus" or thymic deaths. Aspiration too has lost repute as a cause of death. It has been shown to be a common finding in instances of death due to other causes.[4] Suffocation undoubtedly occurs, but the evidence says that most crib deaths are due to infection. Gruenwald and Jacobi[2] found mononuclear pneumonia very commonly in infants who died suddenly after being in apparent good health or who were ill for only a short time. Werne and Garrow[5] had autopsy examinations in three different categories of infant deaths. The first group was thirty-one infants who died suddenly while in apparent good health. The second group was twenty-six infants who were actually observed while they died suddenly while in apparent good health; and the third group was twenty-six infants who died violent deaths. Many of the first group of thirty-one infants were thought to have died from suffocation. Careful microscopic examination of the tissues showed that all the infants had respiratory disease. In twenty-six infants dying violent deaths, evidence of respiratory infection was spotty and mild. In the group of infants who were observed while dying, ten had heart disease or gross bronchopneumonia and the remaining sixteen infants all showed microscopic respiratory infection. The significant points in these studies were:

1. Most sudden deaths in infancy and especially below the age of six months are due to infections.
2. True suffocation deaths are rare.
3. Aspiration is a common agonal event but seldom is the cause of death.
4. Mononuclear cells may be present in the

Dr. Berglund is Attending Pediatrician at the Minneapolis General Hospital.

alveolar bronchiols in several different conditions and are not diagnostic of pneumonia.

Streptococci, staphlococci, meningococci and E. Coli septicemia have all been shown to cause sudden death in infants.[1]

I am confident that most doctors who care for babies have seen instances where suffocation did seem to be the cause of death. The baby is found face down in a soft pillow, or bed clothing is wound about the head, or the head is caught between the rungs of the crib with the face against the mattress, or the baby has slid between the rungs or between the crib and the mattress and the baby has strangled. Some of these deaths can be prevented. The doctor must preach safety in the crib as part of his post-natal instructions to the mother. The mattress must be firm, it must fit the crib well with no spaces on the ends or sides; pillows must not be used. The crib sides should be solid or the rungs spaced closely.

The doctor must also be alert to minor symptoms in the small infant as warnings of possible serious disease. The immune mechanisms of the small infant are poor. Chemotherapy or antibiotic therapy may be prescribed without all the criteria that the conscientious doctor may demand in an older patient.

If death does occur in the crib, then the doctor must try to find the true cause of death. To learn that infection rather than suffocation caused their baby's death may spare the parents profound feelings of guilt. Autopsies should be done on all infant crib deaths.*

Doctors need to be accident-conscious. Accidents kill many more children than diphtheria, tetanus, pertussis and smallpox. The doctor does not consider his work done unless his child patients are immunized against these diseases. He should not consider his care adequate until he has inoculated the germ of accident prevention into both child and parents. This can be done at his office, as part of the first-year, well-baby instructions. Brochures and check-lists to supply to the parent can be obtained from the Minnesota State Department of Health, Section of Maternal and Child Health, University Campus, Minneapolis, Minnesota.

---

*If the services of a local pathologist are not readily available, the doctor may remove tissue specimens and send them to the Pathology Department, University of Minnesota Medical School, where tissue preparations and interpretations of the pathological findings will be made without charge.

Teratoma of the Recto-Sigmoid

S. T. KUCERA, M.D.
Northfield, Minnesota

TERATOMAS are embryonic tumors which are characterized by the fact that they contain tissues from one or all of the three germ layers; therefore they contain skin, hair, bone, cartilage, muscle, teeth, nerve tissue, fat, intestinal mucosa and other organs. There is no order in the arrangement of tissues, as they are a veritable pot-pourri of fetal tissues. The tissues may be adult or embryonal type. The former are prone to give rise to benign tumors, and the embryonal elements are more apt to give rise to malignant tumors. The nature of these tumors can be understood best in the light of their mode of formation. They are apparently due to the partial separation of a part of the ovum in the blastomere stage. The younger the ovum is, the more nearly totipotent its cells are, and the more capable of producing more than one tissue. In the blastomere stage a small part of the dividing ovum is partly separated and continues to live as a mass of cells, attached to the host and causing no disturbance until for some unknown reason this embryonic tissue is stimulated to independent growth. They are therefore faulty efforts at twin formations.

Depending upon the age of the blastomere and multipotency of its cells, teratomas of any simplicity or complexity may be formed. In dermoid cysts, the tissue is more adult and more specialized than in other teratomas; organs are better formed and more adult in type. In other teratomas, the tissue is often completely unorganized, may be a solid mass, and organs are more rudimentary and embryonic. Teratomas may be found anywhere in the body but have a predilection for certain locations, especially the ovary. Teratomas of the posterior rectal wall space were described by Middeldorf as early as 1885 and still frequently are referred to as Middeldorf tumors. Many cases have been reported of numerous variations of this tumor in the medical literature, but nowhere in the American recordings have I been able to find a case of teratoma arising from the mucous membrane of the pelvic colon. One case of dermoid arising from rectal wall was found recorded in the *British Journal of Surgery* by R. Nigam in 1947, in which the author stated that the mass protruded from the anus and was 4 by 2 inches in size. It was attached to the anterior rectal wall by two pedicles one-half inch thick and about 5 inches from the anal margin. There was no obvious connection between the mass and any of the pelvic viscera other than the rectal wall.

Another case was reported in Bland-Sutton's monograph on tumors in 1922 of London, England. They found a pedunculated teratoma hanging from the mucous surface of the sigmoid flexure which led to intussusception in a girl of sixteen years of age.

Dermoids in the wall of the rectum are rarely met with and the majority of cases reported so far have been of the nature of dermoid cysts. The following case is of interest because the tumor was a solid mass containing bony rudiments and glands covered with hairy skin, and microscopically a true teratoma.

Case Report

Mrs. L. P., aged twenty-seven, a white woman, presented herself on January 9, 1953 with the following history:

Since the age of approximately fourteen years this patient had noted a mass presenting at the anus whenever she had a bowel movement. As time went on, this mass became gradually larger and larger producing symptoms of pressure in the rectum; and finally, in recent months, produced so much obstruction that it was necessary for her to push this mass back into the rectum each time before she could evacuate her bowel. She had consulted a physician several years ago after passing blood for the first and only time, and after examination he reassured her there were only a few external hemorrhoids present which did not necessitate any treatment.

The family history was essentially negative. The past

Presented at the Annual Meeting of the Southern Minnesota Medical Association, Winona, Minnesota, September 13, 1954.

history of illness included measles, mumps, and chicken pox. She had had a tonsillectomy at age fourteen. The menstrual onset was at age 11 years, and was regular and normal. Dysmenorrhea was present during the first day. She had been married for eight years and has not been able to conceive to date, even though examination of the husband's sperm was normal.

On examination this patient was a well-developed female 63 inches tall, weighing 146 pounds. The hemoglobin was 11.8 gms. white blood count 7,000, Wassermann negative, and urinalysis negative. General physical examination was essentially normal. The genital pelvic organs were normal except for a large firm mass which was palpable in the rectum through the posterior vaginal floor and on digital rectal examination. On the latter examination, the pedicle attached to the right lateral rectal wall was palpable; the mass seemed to be about the size of a large hen's egg, and there was a sharp calcified structure palpable in one area of this mass. On proctoscopic examination this mass was partially visualized and the pedicle attachment was readily recognized. The passage of a sigmoidoscope was attempted past the mass without success. A flat plate of the abdomen unfortunately was not taken, nor a barium enema study made.

On January 16, 1953 after the bowel had been sterilized for twenty-four hours previously with neomycin, this tumor mass was removed under Pentothal anesthesia. The pedicle arose from the right lateral rectal wall and was about one-half inch in diameter and very short, so that it was almost flat against the bowel wall. The mucosa of the bowel did not extend onto the stem but surrounded it in a manner much like fine sand would surround a mushroom stem. It was difficult to extrude the mass and only after considerable traction was the entire mass presented. The pedicle was clamped flush with the mucosal surface and ligated with chromic catgut, and allowed to retract back into the pelvis.

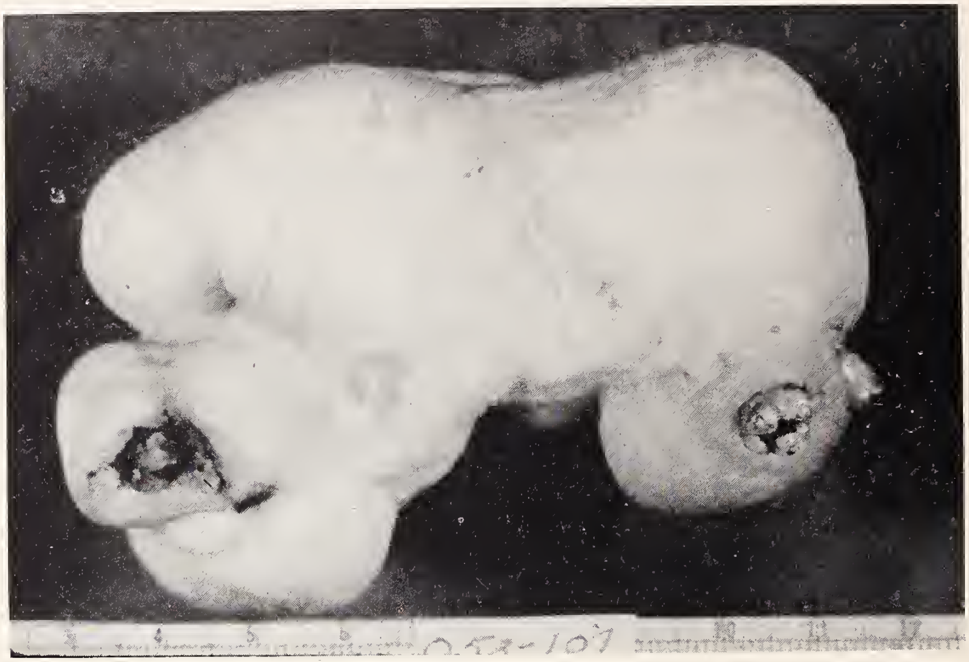

Fig. 1.

The specimen removed consisted of an irregular shaped mass of tissue measuring approximately 9 x 5 x 4.5 cm. in size. It was covered externally by skin from which a number of long fine hairs were growing. At one end there was a protuberant mass from which protruded two molar teeth. Opposite this was a small verrucous area measuring 1 cm. in diameter. On cut section the central portion appeared to be composed primarily of fat and connective tissue. Microscopic examination of sections established this as a true teratoma. The outer surface was covered by tissue having all of the characteristics of skin with hair follicles and sebaceous glands present. A cyst found in the deeper tissue was lined by a pseudostratified columnar ciliated epithelium and small islands of cartilage laid adjacent to this similar to what one would see in large bronchi. The intervening tissue showed fat, callogenous connective tissue and apocrine glands of various types. No evidence of malignancy was found in any of the sections.

Five days after the surgical procedure a sigmoidoscope was passed up to 20 cm. and no sign of the pedicle area was found. A month after surgery a sigmoidoscope was passed 22 cm. and no evidence of scar of previously removed tumor was found.

A barium enema was given six months after surgery, and no evidence of former tumor site or any other abnormality was found. Postoperative course was uneventful and the patient has been well and symptom free since.

DIAGNOSTIC ENIGMAS OF DISEASES OF BONE

ARTHUR H. WELLS, M.D.
Duluth, Minnesota

In most fields of oncology, all eyes turn to the pathologist for the last word—*his histologic diagnosis.* For the recognition of diseases of bone the clinical and roentgenologic consultants are frequently of equal or greater importance. Though there are many clear-cut blacks and whites in the diagnosis of osseous lesions, there exist, on the other hand, unusually large grey areas of frustration. Examples of mutilation resulting from "overdiagnosing" and the fatalities from "underdiagnosing" bony diseases are legend in the annals of pathology. There is probably no group of diseases in the body where the pathologist's ignorance has done relatively more harm. Paucity of experience and rather recent organization of knowledge in the field are partly to blame. It behooves the responsible clinician to know some of the more important weaknesses in the histologic diagnosis of diseases of bone so that he may not be so easily led astray by his most trusted microscopist.

The day is long past when the cellularity of the benign giant cell tumor will lead to an unnecessary amputation. Furthermore, pathologists have learned that the presence of multinucleated giant cells does not establish the diagnosis of giant cell tumor any more than fever is a disease. The combination of fibrous connective tissue and giant cells occurs abundantly not only in giant cell tumor but also in fibrous cortical defects, unicameral bone cysts, osteitis fibrosa cystica, benign chondroblastoma, polyostotic fibrous dysplasia, monostotic fibrous dysplasia, renal osteitis fibrosa, xanthomas and other diseases. The most important errors of diagnosis in this group of diseases of bone include: (1) failing to locate small sites of malignancy in an otherwise benign giant cell tumor; (2) completely ruling out osteitis fibrosa cystica (hyperparathyroidism) without serum calcium, phosphorus and phosphatase analyses; (3) making a prognosis as to the possible future recurrence and malignant changes from a histologically benign giant cell tumor; (4) not recognizing the potentially dangerous benign giant cell tumor because of much hemorrhage and degenerative changes in the lesion and (5) misjudging in either direction a giant cell tumor of bone with histology in the borderline of malignancy.

Many limbs have been unnecessarily amputated because of the presence of benign, cellular, growing osteoid tissue. A list of the various benign conditions misdiagnosed as osteosarcoma certainly would include, among others: myositis ossificans, osteoid osteoma, exuberant callus of fractured or otherwise traumatized bone, ossifying displaced periosteum, Caffey's disease, Garré's osteitis, syphilitic osteitis, polyostotic fibrous dysplasia, monostotic fibrous dysplasia, ossifying bursitis and Charcot's joint. One fourth of the written diagnoses of pathologists at the 1953 annual tissue seminar of the American Society of Clinical Pathologists listed the slide of myositis ossificans as osteosarcoma. On the other hand, the pathologist may mistake osteosarcoma for any one of these benign lesions listed above. As in other neoplasms, borderlines between benignancy and malignancy in a small percentage of osteoblastic lesions are impossible to determine. This is especially true in the parosteal bone tumors.

An unusually difficult histologic diagnostic problem exists in the potentially dangerous enchondromas of long bones. It is entirely possible today that competent pathologists have a tendency to "overdiagnose" these enchondromas, while the inexperienced may fail completely to appreciate the importance of the subtle changes of edematous degeneration of the matrix, multiple cells per lacuna, and plumpness of nuclei found in the low-

---

From the Department of Pathology, St. Luke's Hospital, Duluth, Minnesota.

This is the twenty-fourth in a series of editorial reports sponsored by the Minnesota Society of Clinical Pathologists and designed to foster closer relationships between clinicians and pathologists.

grade malignancies of cartilage. This paradox is emphasized by the necessity for immediate radical surgery of chondrosarcoma, no matter what its histologic grade of malignancy. Most pathologists must depend on utilizing the experience of others for the proper evaluation of many of these rare diseases of the skeleton. The fact that only isolated focal areas of malignancy may be present does not help solve this diagnostic problem.

Neoplasms arising from cartilage cells in other bones for the same reasons may be difficult to classify. In a series of forty patients treated in a large Minnesota medical center for what was originally considered histologically benign chondromata, nine died of their malignancy and eight had recurrences. The destructive and cellular benign chondroblastoma may lead both the roentgenologist and the pathologist to advise radical surgery. At the seminar cited above, one third of the pathologists voting listed this nonmetastasizing lesion as malignant. There may be an abundance of immature cartilage in the callus at the site of a march fracture. The cartilage in an enchondroma of the phalanx may have startlingly large nuclei and be unusually cellular with evidence of bone destruction and yet be benign. These and other difficulties may becloud the histologic interpretation of neoplasms of cartilage.

There is a long series of miscellaneous booby traps set in the path of the histologic recognition of lesions of the skeleton. Some of the more important of these include: (1) mistaking a cellular fibrocytic reaction at the site of an osteomyelitis for fibrosarcoma; (2) being deceived by the large closely compact cells of a bone-destroying benign xanthoma; (3) advising an unnecessary radical cr disfiguring operation for the nonneoplastic disease, polyostotic fibrous dysplasia; (4) considering the frequently destructive and large aneurysmal bone cyst malignant and (5) failing to recognize the secondary nature of a bony lesion metastatic from occult primary malignancy. A patient with a cavernous hemangioma of the tibia refused to have his leg amputated for "cancer" in one hospital. In a second institution, the condition was diagnosed by biopsy and x-ray examination as Paget's disease. Here the man may well have lost his leg as the result of therapeutic procrastination. In a third hospital, a diagnosis of cavernous hemangioma was made and he was given radiation therapy for the benign but progressing vascular disease. After ten years, he appears to have recovered.

Conclusion

Four basic rules should be listed so that the responsible clinician will get the most out of his pathologist consultant for the patient with a bone disease:

1. Do not overestimate the value of the histologic diagnosis.
2. If there is any question of diagnosis, the pathologist will welcome "outside" consultations. The best and the most experienced minds of pathologists in the country are available without charge.
3. Present the pathologist with all of the clinical and roentgenologic evidence; he may be lost without it.
4. The clinician should know the principal areas of uncertainty in this difficult field of microscopic pathology.

The pathologist is responsible for his own diagnosis. He should not make many serious mistakes before he recognizes most of his personal limitations and the range of accuracy of the methods of his specialty on his battle line of practical experience.

MODERN MEDICINE AND MORBIDITY

The data which witness modern medicine's triumphs, the statistics that reflect the declining death rates and the increase in life expectancy (at birth), when critically examined add up to the summation that modern medicine has in a large measure converted mortality into morbidity. Those whose lives it has helped to save in many instances face not an extension of existence in well-being and in health, but merely a prolongation of endurance. Those who by the skills of modern medical science have been saved from death all too often have been saved only to longer endure the burdens of a variety of illnesses, and to die at a later age. In the statistical tabulations such individuals appear to have gained years of welcome life, but these may be, and too often prove to be, years of painful travail, years of dependency, unproductive years which in the last analysis are social and individual liabilities rather than assets.—Iago Galdston, M.D., "The Meaning of Social Medicine," Harvard University Press, 1954.

Clinical-Pathological Conference

CASE PRESENTATION

ARTHUR C. AUFDERHEIDE, M.D.

Clinical History

The patient, a sixty-seven-year-old white man, retired woodcutter, was first admitted to St. Mary's Hospital May 7, 1954. Complaints were nocturia, difficulty starting stream and gross hematuria for one and one half months. Hematuria had been severe. He had lost weight from 250 pounds to 180 pounds in the preceding two years, ascribed to voluntary dieting resulting from accompanying dyspnea during that time. Anorexia had been present for the past several months but no abdominal pain. Past history, family history and system review was negative. Physical examination showed a few small hemorrhages in the oral mucous membrane; otherwise the eyes, ears, nose and throat were not abnormal. Several bean-sized hard nodules were palpable in the supraclavicular areas in each side. Except for occasional premature contractions the heart was not abnormal. The liver was palpable 4 cm. below the rib margin in the right midclavicular line, but was not tender. The extremities and reflexes were not abnormal. Rectal examination showed an enlarged, hard, nodular prostate gland. An attempt was made to pass a catheter but failed.

Laboratory findings are shown in Table I.

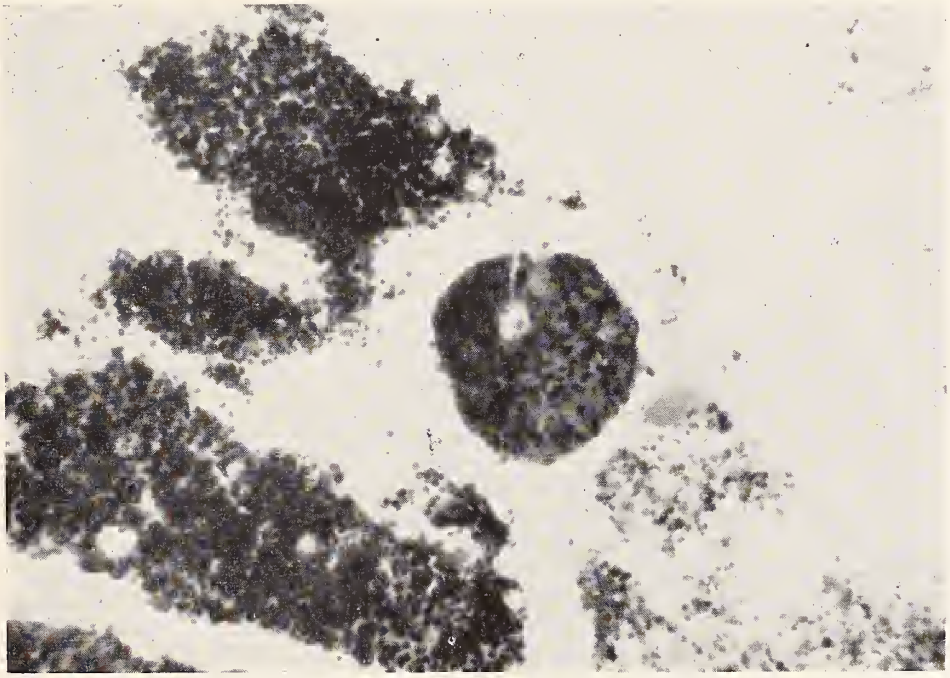

Fig. 1. Histologic section of bone marrow particles (from the bone marrow aspiration specimen performed antemortem) showing metastatic carcinoma. Hematoxylin and eosin, ×425.

On the day following admission 2500 cc. of blood were given the patient. The same day a suprapubic catheter was put in place; bloody urine was draining freely when the patient left the operating room. A radiograph including the kidneys, ureters and the bladder showed arthritis, but no evidence of metastatic malignancy. On May 10, another 2500 cc. of blood were given, but the pubic drain clogged and a urethral catheter was passed successfully which drained more bloody urine. On May 11, 6300 cc. of blood were given and a bone marrow aspiration performed. Serious bleeding occurred for at least twenty-four hours from the sternal puncture wound. The bone marrow was reported as showing erythroid and myeloid hyperplasia in the bone marrow and thrombocytopenia in the peripheral blood. Megakaryocytes were numerous and not abnormal morphologically. Histologic sections of marrow particles showed metastatic carcinoma (Fig. 1). In the afternoon, on May 11, the patient again passed into severe shock. Noradrenalin, digitalis, and intravenous aminophyllin were given. The skin appeared jaundiced. ACTH was started.

Additional history at this time revealed a past history of chronic alcoholism for many years. The patient continued to bleed severely until about June 2, when bleeding lessened markedly. By June 10, only a tinge of

Edited by Donald Gleason, M.D., under the auspices of the Minnesota Society of Clinical Pathologists.

blood was seen in the suprapubic discharge. On that date, auricular fibrillation at a rate of about 100/min. was noted. The patient suffered dyspnea and had demonstrable leg edema. Râles were heard in the lower chest posteriorly. Clinically, he was much better and much more alert. On June 11, rectal examination revealed the prostate to be somewhat smaller, probably as a result of the stilbestrol therapy which had been administered since admission, but it was felt that the decrease in size was mild. The patient expired on June 14 at 4 a.m. Earlier that evening, even though he had been improving, he awoke at 11:20 p.m., very confused and soiled himself with a large loose stool. He complained of pain in the throat and chest pain. He was very restless and passed several more loose stools. He became irrational, and respirations were rapid and labored. He obtained slight relief from opiates and expired quietly.

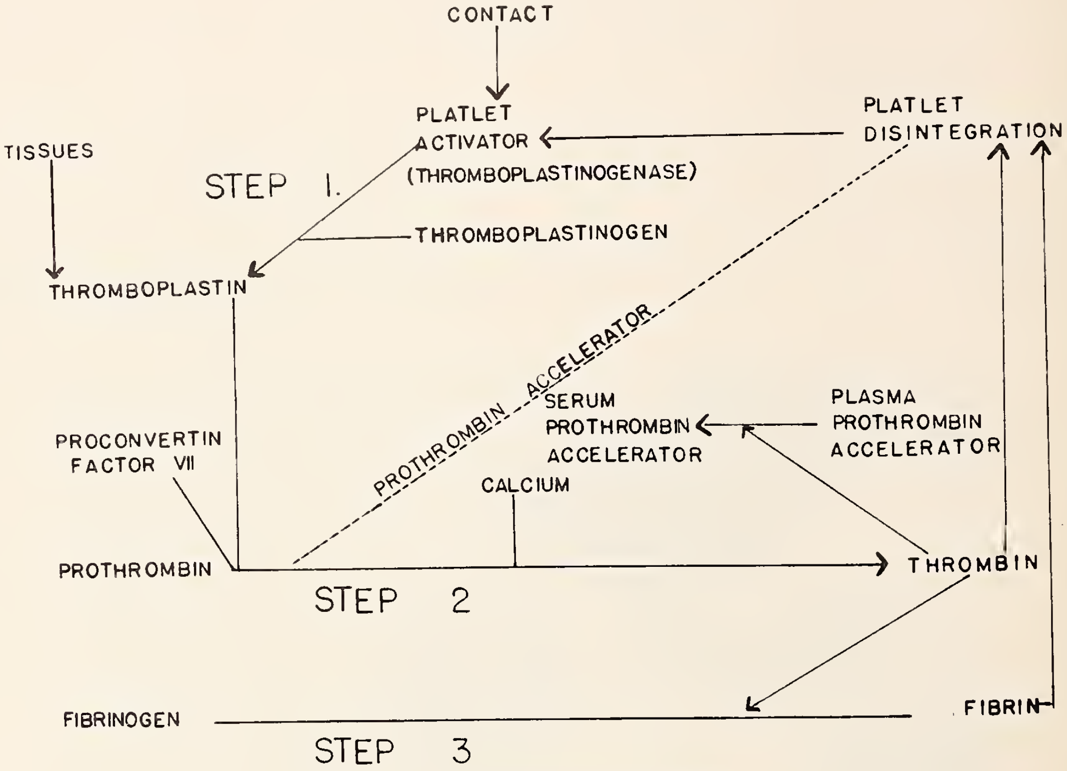

Chart 1. (Adapted after Stefanini[5])

Discussion

Dr. Robert Goldish (Duluth): It is worthwhile to consider briefly blood coagulation in general and how it relates to the present case. Pertinent methods of "screening" hemorrhagic disorders include a careful history and physical examination, detailed study of the family history, bleeding and clotting time, clot retraction, platelet count, prothrombin time, and capillary fragility test. Caution and perspective must be exercised in interpreting these laboratory tests. The laboratory technique must be standardized and the tests performed with care and controls, since seemingly minor variations in technique can cause grossly misleading variations in results. For instance, just to mention one or two variations which may be quite common, a falsely prolonged bleeding time may result from too deep a puncture, and—in some laboratories, at least—the coagulation time done by the Lee-White method may normally run as high as twenty minutes.

Quick's prothrombin consumption test is actually a measure of available thromboplastin, comparing the prothrombin time of plasma and of serum to determine how much prothrombin was consumed in clotting. Normally, about 80 per cent or more of the originally available prothrombin will be consumed in clotting, while in hemophilia or thrombocytopenic purpura (where thromboplastin production is decreased) as much as 90 per cent may *remain* in the serum after clotting. Many other more specialized tests may be used, and at times it becomes necessary to study blood samples from the patient's relatives.

In 1905, Morawitz established the classical theory of blood coagulation which recent concepts have not contradicted but merely expanded. Morawitz postulated that prothrombin was converted to thrombin through interaction with calcium and thromboplastin; thrombin then caused fibrinogen to form fibrin. Much of the current confusion is probably due to the fact that different investigators independently discovered similar or identical phenomena simultaneously, resulting in a turmoil of nomenclature. Nevertheless, most investigators[5] agree on the following four points: (1) thromboplastin activation is a separate, preliminary phase in thrombin formation *in vivo;* (2) factors in addition to thromboplastin and calcium are involved in the conversion of prothrombin to thrombin; (3) serum contains one or more agents accelerating prothrombin to thrombin

* One stage prothrombin method of Quick. Endpoint recorded on May 13, 14, and 16 was appearance of a few fine greyish strands which disappeared in a few seconds. They might better be recorded as 0%. Addition of thrombin produced no better clot, but addition of one drop of normal serum produced a clot in 12 seconds.

** Test performed by placing freshly clotted patient's blood in 37° incubator for 1 hour; disappearance of clot reported as positive test.

conversion; (4) the formation of thrombin proceeds as an autocatalytic, progressively accelerating process.

The first phase of blood coagulation concerns the production of thromboplastin (Chart 1). This substance may be formed either by release of formed thromboplastin from injured tissues or by interaction of plasma constituents with products contributed by lysed platelets. Platelet lysis occurs upon contact with certain surfaces such as disrupted tissue, air or glass. The material released from lysed platelets (platelet activator; thromboplastinogenase) reacts with a substance normally present in serum (thromboplastinogen: antihemophilic globulin; AHG) to form thromboplastin. Thus, platelet deficiency would result in decreased thromboplastin formation. It has been noted recently[6] that AHG is not the only substance necessary to combine with material from lysed platelets to form thromboplastin; at least one other substance (plasma thromboplastin component; PTC)[4] and perhaps two (plasma thromboplastin antecedent; PTA) have been identified.

Phase 2 of blood coagulation is concerned with conversion of prothrombin to thrombin. Thromboplastin and calcium will combine, perhaps along with other factors, with prothrombin to produce a small amount of thrombin, insufficient to activate fibrinogen. An accelerating factor present in the plasma as an inert substance (plasma AC-globulin, proaccelerin, factor V) rapidly becomes active as a serum prothrombin accelerator in the presence of thrombin.[3] Thus, the initially formed small amounts of thrombin activate the accelerator substance which, in turn, "speeds up" the conversion of prothrombin to more thrombin eventually to produce enough of the latter for fibrinogen activation. A second, less well-defined prothrombin accelerator has been described and has been named stable factor.[2,3]

Phase 3 is universally conceded to be a simple enzymatic process in which fibrinogen is converted into fibrin by thrombin, aided perhaps by other accelerators, such as those of platelet origin.

Further details of interest include the possibility that platelet lysis may be enhanced by thrombin, fibrin, or both; the release of a locally acting vasoconstricting substance, (serotonin), from lysed platelets and the release of other prothrombin accelerating factors from lysed platelets. Anticoagulating substances are also normally present; antithromboplastin, antithrombin, and even fibrin itself all act as buffers to the process of blood coagulation. It should be pointed out that Vitamin K has no effect on prothrombin other than to enable the liver to form prothrombin.

In the application of these concepts to the case at hand, several features are important. Shortly after admission, thrombocytopenia and prolonged prothrombin time were noted. Although there are suggestions in the literature that the two may be associated, I do not understand such an association since possible thromboplastin deficiency *in vivo,* which might be expected from thrombocytopenia, ought not to affect the simple one-stage prothrombin time determination, in which thromboplastin is deliberately added in excess.

Stefanini[5] has reported a case, in which this association was noted (secondary thrombocytopenic purpura) and in which he showed not only thrombocytopenia, but also decreased prothrombin accelerator factors, explaining the delayed prothrombin time on the coincident occurrence of the accelerator deficiency.

In the present case, the addition of a drop of normal plasma to the patient's plasma resulted in a normal prothrombin time, suggesting that no circulating anticoagulant was present in sufficient quantities to prevent prothrombin activity. The protamine titration, a test to determine the presence of a circulating heparin-like compound, was also normal. Yet when the thrombin was added to the patient's plasma no clot formed, even with the addition of thromboplastin and calcium (not normally needed to convert fibrinogen to fibrin in the presence of excess calcium). I do not understand this finding in the face of a normal coagulation time.

The presence of fibrinolysin may be significant. This is a substance which can cause dissolution of a clot. The fibrinolysin system has been incompletely described. The following scheme seems to be established thus far.[5] Profibrinolysin normally present in the plasma may be activated to fibrinolysin by an enzyme (fibrinolysokinase). This system is normally held in check by an antifibrinolysokinase and an antifibrinolysin. It is probable that fibrinolysin was present in excess quantity in the case we are discussing and that it may have been responsible, not only for the clinical hemorrhage, but also for the failure of a clot to form when thrombin was added to the patient's plasma *in vitro*. Carcinoma of the prostate has been reported to produce excess fibrinolysin. Furthermore, Wintrobe[7] and others report the suggestion of activation of the fibrinolysin system by the stress phenomenon, and that antifibrinolysin may be stimulated by ACTH, a drug the patient was receiving. Fibrinolysins have also been described in cases involving placental separation, transfusion reactions, and in bleeding diatheses associated with leukemias and cancer of various organs.

In summary, I think this patient had a prostatic carcinoma with widespread metastases including the bone marrow, with resulting secondary thrombocytopenia and excess circulating fibrinolysin. The situation was probably controlled, at least partially, by steroid therapy which the patient received.

Doctor Goldish's Diagnoses

Hemorrhagic diathesis, due to:

Thrombocytopenia, secondary, and excess circulating antifibrinolysin, due to:

Carcinoma of the prostate with widespread metastases.

Anatomic Diagnoses

Adenocarcinoma of the prostate with multiple metastases.

Widespread metastases to bone marrow.

Dr. A. C. Aufderheide (St. Mary's Hospital): At autopsy the heart weighed 500 grams, but except for mild coronary arteriosclerosis showed no further ab-

President's Letter

THE CORNERSTONE

The county medical society is the basic cornerstone of medical organization. Just as a great and impressive building must have a firm foundation, replete with strong cornerstones, so the state and national medical organizations must have a firm foundation in strong county medical societies.

It is very difficult for medicine's critics to realize that the state and national groups have no power over the county medical society, and can dictate to it in *no* way. Medical organization is a confederacy, not an autocracy. Those who picture the AMA as a gigantic, all-powerful trust, are laboring under delusions; the state and national groups do not enter a county society problem unless specifically requested to give help.

The extensive value of a county medical society cannot be overemphasized. It is the entrance port for membership in the state and national organizations. A member of the county medical society and the state medical association does *not* have to be a member of the American Medical Association.

To my mind, one of the most important projects of the local society is the proper preparation and reception of new members. It is in the county medical society that the new member becomes aware of his many obligations, as well as his privileges—these are necessary things if the new member is to fulfill the ideals of what the practicing physician should be. In practical terms, the county society is the character-building organization, to the end that the nation and the profession are well served.

The job of informing long-time, as well as new members, is that of the county officers. They must keep themselves aware of the larger problems of state and national medical organizations. They can be aided by the conscientious efforts of state officers, councilors and AMA delegates to report the decisions and discussions carried on at a state and national level. The membership in general can be kept well informed by discussions at annual meetings with officers on problems of membership, programs, mediation committees, and the many varied activities of medical organization. One of the most valuable of these meetings is our recent County Officers' meeting, held to acquaint and re-acquaint county officers with the sometimes intricate, but always interesting, procedures and policies of the state and county organizations.

Another important and recurrent problem is how best to stimulate the "old" member to assume more active interest in his local society. I fear that there are too many who are simply "going along for the ride." How immeasurably more pleasant and satisfactory would be the work of the officers of the state and county organization if every one of our members took the active interest he or she should.

It would be hard to evaluate the worth of such interest, both to the public and the profession. Truly, the county medical society is, and rightly should be, a strong and indomitable cornerstone of medical organization. It is upon this solid foundation that the state and national groups depend for a secure base, for if it crumbles, the entire structure could be seriously impaired.

THE DOCTOR AS A WITNESS IN INDUSTRIAL COURTS

The doctor is a highly important witness when testifying as an expert in his chosen profession before a referee of the Industrial Commission in a workmen's compensation case. He is called because of his knowledge gained through study and experience in a particular field of medicine. His testimony is not above being challenged by other experts in the same field, nor is it beyond being questioned or disbelieved by the average layman.

This leads to one thing: the expert witness, regardless of whatever field of endeavor in which he is qualified, must be prepared for the rôle he is to take, and his testimony must be straightforward and unbiased.

If the doctor has treated the patient, keeping complete medical records and having them while testifying is of the utmost importance. Without records, how can a medical witness testify as to the first day the patient came to him as a result of injury or illness? Unless the doctor has a superhuman memory, how can he recall what the patient's complaints were, what examination was made and what treatment given? History is essential as a part of the doctor's records, not only from the standpoint of care and treatment, but also for future reference, should litigation or a claim arise because of a trauma or occupational disease the patient may have suffered, which resulted in his need for medical attention. These records should cover not only the first visit, but subsequent visits, right down to the day of discharge. The first entry in the record in most cases, of necessity, will be quite detailed. Entries covering subsequent visits may be shorter, but not so sketchy that they do not contain the patient's symptoms, complaints, prognosis or treatment. Mere dates of visits are not enlightening.

A medical witness, as well as any other expert, must testify to the facts as he understands them to be. His testimony to be of value must be unbiased and his opinions based on sound medical principles backed by his knowledge and experience. To color one's testimony in favor of one side or the other in a dispute is unforgivable. The trier of facts soon becomes aware of the witness who does so and consequently his testimony is discounted to that degree. His efforts to become an advocate for one of the parties does not reflect credit upon himself or his profession, nor does it redound to the benefit of the recipient of his efforts. The medical witness who expresses his honest opinion, regardless of whether it is favorable to the party who calls him or to the opposing side, is the most valued and most respected in the eyes of the trier of fact. Medicine not being an exact science, very often it is impossible to make an exact diagnosis, either because of lack of experience on the part of the doctor in a particular field, or because the problem is so controversial that several diagnoses may be made. In such a situation, the expert witness should make a straightforward statement that he does not know, or give a qualified opinion, based on sound medical principles, of his knowledge as to what the diagnosis may be. If he pursues this course, the trier of facts will have much greater respect for him and give greater credence to his testimony, than if he engages in specious theorizing.

Norbert Willwerscheid
Chief, Division of Workman's Compensation

THE PHYSICIAN AND HIS BUSINESS INSURANCE

The medical men, by the very nature of his profession, has made himself vulnerable to both loss and abuse. If he is successful financially, there are many ways by which his future can be impaired. His possessions may be damaged, destroyed or stolen. His financial future may be ruined through claims brought against him charging malpractice.

By the very nature of a medical man's training, he is keenly aware of the value of professional or expert advice. If the physician's problems, insurance-wise, were laid fairly before a competently qualified insurance man, the problem of securing and preserving his economic status could be completely and adequately assured.

There are many exposures facing the physician today. In his business alone, great strides have been made to satisfy these needs. New and complete coverages have been devised to cover the actions of the doctor, whether he be acting professionally or in a personal manner. The fine equipment which graces his office or clinic also must be insured properly to hedge against a disastrous loss. The following list of coverages may or may not apply to each individual physician. They should, however, be given very careful consideration.

On building and contents coverages are available for:

Fire and Extended Coverage
Vandalism
Rent or Rental Value
Improvement or Betterment
Radium
Physician's and Surgeon's Instruments
Signs
Glass
Boiler and Machinery
Extra Expense or
Business Interruption

Under the professional activities, we find:

Premises Liability
Malpractice
Comprehensive Personal Liability
Office Burglary
Fidelity Bonds
Automobile Insurance
Non-Ownership Liability
Workmen's Compensation

Since both financial and professional ruin contantly face the physician today, he needs the best of help in choosing the specialized forms which are available for his protection. Again, we should repeat that the best insurance agent costs no more and it is of great importance to consult an agent of good reputation, one who represents insurance companies today that will have financial strength to take care of claims that will come in the tomorrow.

Ernest Collingham

SIGMOIDOSCOPIC EXAMINATIONS

Lord Dawson of Penn visited the United States in 1923, and, in one of his addresses, made the statement that in doing physical examinations, "if one did not put his finger in the rectum he would be certain to get his foot in it." That statement marked the beginning of the popularity of the digital rectal examination as a part of every physical examination. No longer was the performance of a rectal examination the sole province of the consultant. Pathology of the rectum and lower colon was brought into the reach of the general practitioner as well as the specialist, and better diagnosis and treatment resulted. Today, the public, as well as the medical profession, is interested in earlier diagnosis of serious lesions and in the early detection of precancerous growths. No longer is the digital rectal examination considered an adequate investigation of the rectum and lower sigmoid colon, since many lesions, particularly the precancerous ones, cannot be felt. Only by means of a well-performed sigmoidoscopic examination can early lesions of this part of the bowel be visualized. Reports from all cancer detection centers are uniformly impressive in pointing out the importance of sigmoidoscopy. Since approximately 10 per cent of all adults harbor precancerous polyps in the rectum and lower colon, the need for early detection cannot be overemphasized.

The time has come when we can state with didactic assurance that no general physical examination can be considered complete without the visualization of the interior of the rectum and lower sigmoid colon. The time has arrived also when accredited hospitals should no longer condone the performance of anorectal surgical operations on patients who have not had sigmoidoscopy.

Medical schools and teaching hospitals must assume the responsibility for the teaching of sigmoidoscopy to students, interns and residents. Physicians in practice should acquaint themselves with the technical aspects of sigmoidoscopy and should make this important examination available to their patients. When sigmoidoscopy is performed as a routine procedure in all complete physical examinations, the cancer detection program will have received one of its greatest lifts.

Wm. C. Bernstein, M.D.

"NEW OCCASIONS TEACH NEW DUTIES"

With the advancement of medical practice from the horse-and-buggy to the jet-plane age, the activities and setting for practice have been affected for nurses probably more than for any other group. Shall we look at some of the trends in nursing in which this advancement in medicine has played a part?

1. *Extension of the Physician's Service.*—

Whereas, formerly the physician looked to the nurse for provision of a simple service devoted primarily to physical care of the sick, the modern physician tends to rely on nursing for a much more complex type of nursing care—physical, mental, emotional, and spiritual. It should be borne in mind that he expects care of all ages with increasing emphasis upon middle, later life and long-term illness and not only care of the sick, but also of the convalescent and the well. And, whereas the nurse of earlier years was found usually in hospitals or with private patients, the nurse of today appears wherever there are human beings: in institutions of various kinds; in homes; in public health agencies such as visiting nurse services, clinics for the aged and group practice, diagnostic, child, and other types of clinics; in schools; college and university health services; in industry; in doctors' offices (35,000 in 1951); in admission and related services; in transportation; in the military; in departments, schools and colleges of nursing. Limitless, indeed, in type of care, of patient, or of locale are the opportunities of the nurse to extend the service of the physician.

Co-ordination of Service.—Just as in medical practice the physician has tended to share his increasing responsibilities with many types of personnel, among them the roentgenologist, the nutritionist, the social worker, the clinical psychologist, the mental hygienist and the nurse—so also has the nurse found it necessary to share her earlier functions with others: the practical nurse, nurse's aide, or other appropriate personnel. In 1952, for example, there were 70,000 more nonprofessional than professional nursing personnel in hospitals registered with the American Medical Association. This sharing in nursing, as in medicine, has resulted in the development of a team of workers—in the one, the comparatively small nursing team; in the other, the more comprehensive health team. Requisite to effective functioning of either group, as in baseball or football, is co-ordination of the efforts of all members of the team to the end that maximum use is made of every member and optimum patient care results.

Improvement of the Quality of Service.—Among the factors contributing to improvement of nursing is recognition of the unique contribution of the individual and of good human relationships. In the field of nursing as in other fields, where studies have been made, a correlation has been found to exist between recognition of the worker and the quality of the worker's service. In the opinion of many, the physician, by doing increasing co-planning with other personnel, is giving them status, and the end result is better patient care. Studies of human relationships in hospitals being made currently by Dr. Leo Simmons of Yale University throw into clear focus the increasing attention being given to this whole area and give earnest of improvement of service through improved interrelationships.

To safeguard the patient's care in today's complex medical practice, to best extend the physician's service and co-ordinate all service for the patient as well as to improve the quality of nursing—all of these have portentous implications in the preparation of the professional nurse. Entrants to professional schools of nursing must be of professional calibre. They must have general as well as professional education. They must know not only skills and techniques, but equally important they must have knowledge and understanding of what they are doing and why. In short, the new occasions and duties in nursing demand that the nurse have education for a profession with increasing status and recognition, one whose members are equipped for responsible partnership on the health and nursing teams, who are skilled in developing and maintaining effective interpersonal and group relationships and who are prepared for useful personal, family, and community living.

ACCIDENTS, THE KILLER OF CHILDREN

Suffocation

In this issue, your attention is again directed to another in the series of articles on Accidents, the Killer of Children in Minnesota. The author highlights icebox deaths—let each doctor help to maintain Minnesota's perfect record; hangings—we have several every year; and suffocation or crib deaths—let us be a little more careful in applying this diagnosis.

Dr. Berglund's comments are well worth your reading time.

The Dean's Page

DISTINGUISHED SCIENTISTS JOIN FACULTY

Since last July 1, three distinguished scientists have joined the Medical School faculty as professors in their respective department. Since each of them fills an important post, members of the medical profession in the state will be interested in learning something of their backgrounds.

On July 1, Dr. Arnold Lazarow succeeded Dr. E. A. Boyden, as Professor and Head of the Department of Anatomy. Dr. Lazarow had been Associate Professor of Anatomy at Western Reserve University School of Medicine since 1948. A graduate of the University of Chicago, where he obtained both the M.D. and the Ph.D. in Anatomy in 1941, he had been associated with Western Reserve's Department of Anatomy in various capacities since 1943. There he was recognized as an outstanding teacher and investigator. Much of his experimental work has concerned diabetes mellitus which he has studied extensively from histological, histochemical, and biochemical standpoints.

A member of Phi Beta Kappa, Alpha Omega Alpha, and Sigma Xi, he also holds membership in the American Association for the Advancement of Science, the American Association of Anatomists, the Society for Experimental Biology and Medicine, the American Diabetes Association, and the Society of General Physiologists. He is, indeed, a worthy successor to a most distinguished scholar.

Also on July 1, Dr. Ivan D. Frantz, Jr., became the George S. Clark Research Professor of Medicine. Dr. Frantz, a 1941 graduate of Harvard Medical School, prior to coming here was Associate in Medicine at Harvard Medical School, Tutor in the Biochemical Sciences at Harvard University, Assistant Physician at Massachusetts General Hospital, and Consultant in Biophysics at Massachusetts Institute of Technology. He was associated with Harvard Medical School from 1946 to 1954. His research work has dealt primarily with various phases of protein and cholesterol metabolism.

Dr. Frantz is a member of the American Society for Clinical Investigation, the American Association for Cancer Research, and the American Society of Biological Chemists.

On December 16 a distinguished alumnus of the Medical School, Dr. John A. Anderson, returned to his alma mater as Professor and Head of the Department of Pediatrics. Dr. Anderson, a native of Sioux Falls, South Dakota, graduated in 1933 and served his internship at the University of Minnesota Hospitals. After further training and research work in pediatrics in Denver, Colorado, he returned to Minnesota in 1937 where he was a member of the faculty of the Department of Pediatrics until 1943. From 1943 to 1949 he organized and served as head of the Pediatrics Department at the University of Utah Medical School, and since 1949 he has held a similar position at Stanford University Medical School.

Dr. Anderson succeeds as Head of the Department of Pediatrics Dr. Irvine McQuarrie, who requested that he be relieved of administrative duties in order to devote his remaining five years on the faculty to teaching research and writing. Dr. McQuarrie was recently honored for his twenty-five years of outstanding service to the University.

The Medical School is indeed fortunate to be able to add men of the caliber of Doctors Lazarow, Frantz, and Anderson to its faculty. I hope that members of the Minnesota State Medical Association will have an early opportunity to meet each of them personally.

COMPULSORY HEALTH INSURANCE ENACTED FOR SWEDEN

A compulsory health insurance plan went into effect January 1 in Sweden. It will be jointly financed by the insured persons, employers, and the government. Information on the plan is explained in a recent issue of a news letter from the Research Council for Economic Security.

The letter states these figures on shouldering the costs of the plan: "Insured persons will pay 44 per cent of the cost; employers, 29 per cent; and the state, 27 per cent. The state's portion will be passed on to tax bills and thus absorbed by the higher-income earning groups. The total cost of the first year's operation of the insurance plan is estimated at $144 million."

Who Pays?

According to the article in the news letter, state health insurance premiums must be paid by every person above the age of 16 who has a taxable income of at least $233 a year. In Sweden, this would automatically blanket in virtually all of the population with the exception of those receiving national old-age and disability pensions. "Persons earning over $3000 a year can carry an additional amount of insurance if they so desire," the letter goes on, "and will be entitled to larger sick benefits. On an annual income of $1750, the health insurance premium is $25.22 yearly."

Benefits Outlined

Among other broad benefits, the plan provides maternity protection for working women. "Expectant mothers will receive 65 to 70 per cent of their normal earnings during the compulsory maternity leave," the letter states. "All mothers will receive a bonus of $52.38 for child-birth, in addition to free public-ward confinement in hospitals, or free obstetrical care at home."

Fees Noted

Fees for physicians will be reimbursed 75 per cent up to a set ceiling, as will fees for dental work in clinics, high schools, and hospitals. Public-wards will be free. Transportation to and from the hospital, or by the doctor to and from the patient's home, will be reimbursed wholly or in part. Certain medicines will be furnished free of charge and others at reduced prices.

Apparently this news letter information was based on a report in the *New York Times* by George Axelson who stated that "the project has split the Swedes," especially the medical profession. He said, "Some physicians fear that work will be doubled or tripled, and that half their time will be taken up with filling out forms and complying with other 'red tape' requirements. The majority of practitioners, however, are observing a wait-and-see attitude."

NEW GROUP TO STUDY HEALTH PLANS

Newly organized is a commission to study various types of plans through which the American people receive medical services. The group, composed of thirteen American Medical Association members, was announced at the clinical meeting of the AMA in Miami in December. A comprehensive survey is to be made by the commission, which will require at least a year to complete.

Member from Minnesota

Representing the AMA's House of Delegates is Dr. Frank J. Elias of Duluth; Dr. Leonard W. Larson of Bismarck, North Dakota will head the commission. In announcing the group's formation the chairman of the AMA Board of Trustees, Dr Dwight H. Murray, Napa, California said, it will have a direct bearing on the improvement of health benefit plans now offered to the American people.

Dr. Larson noted, "Because of the great interest in medical care plans at present, on the part of physicians, the federal government and the people, the American Medical Association has felt for some time that a complete factual study of all types of plans was needed. The survey will include both medical and lay-sponsored plans."

He also stated that the new commission will inquire into the nature and operation of medical service plans, the quality of medical care provided, as well as the legal and ethical status of the various arrangements now being used.

LEGION COMMANDER ADDRESSES M.D.'s

The AMA and the American Legion have agreed to try to reach a common ground on their differences.

Speaking at the AMA clinical session in Miami last December, Seaborn P. Collins, national Legion commander, offered to appoint a committee to meet jointly with an AMA-appointed committee to study these differences and try to work out some sort of solution to the debate on the VA program for non-service-connected disabilities.

In his talk before the House of Delegates, Mr. Collins pointed out that, in spite of recent differences, both AMA and the Legion are committed to the "common objectives of strengthening the security of our nation and the welfare of all of our people."

Mr. Collins urged the AMA to consider the Legion's viewpoint on the matter of service-connection. He stated:

> "The American Legion neither expects nor wants the Government to give carte blanche entitlement to medical care to all veterans. We have not asked for it. The VA's goal now is 128,000 beds—for more than 20 million veterans. We are not seeking any major increase in this goal.
>
> "At the same time, the American Legion does not want to see any war veteran who is sick and in need go without proper treatment. We know the medical profession doesn't, either. Further, we believe that the war veteran with honorable service has earned such necessary treatment from the Government he served."

In summary, Mr. Collins declared:

> "The American Legion and the American Medical Association are united in our separate determination to protect this nation from the insidious, destructive forces of Communism. We are united in our determination to secure for America an adequate, economical program of national defense. We are united in our determination to imbue our citizens with a fierce love of their Country and an abiding faith and confidence in the imperishable principles that are our heritage. . . .
>
> "Let us make certain that nothing ever comes between us to imperil this essential unity of purpose and action."

PUBLIC SERVICE EXPLAINED BY DOCTOR HESS

The president-elect of the American Medical Association, Dr. Elmer Hess, gave the keynote address before the PR conference at the Interim session of the AMA in Miami. His address, distinguished and comprehensive, carried many thoughts on what public service means, his key point being that personal sacrifice is the center of such service.

In bringing up this point, Dr. Hess quoted a seventy-two-year-old statement by an Illinois physician:

> "The amenities of professional intercourse, and the obligations of medical men toward each other and the public, were perhaps better observed in 1850 than now. Then the doctor, next to the minister, was the trusted friend and counselor of every family to whom he ministered. He shared their joys, soothed their sorrows, and every passing year added to and cemented the attachment of affection between them. Now the doctor is regarded more in the light of a tradesman or mechanic, and is employed from the same consideration that a grocer, tailor or shoemaker is. The strong ties of gratitude and affection have almost ceased to exist. Relationship is now placed upon a mere commercial basis, and for this the profession is more to blame than the public."

In spite of the age of this quotation, its application to medicine today is just as correct, and bitingly so. Although the field of public relations seems to many of us of fairly recent development, Dr. Hess noted, the attempt to bring the profession into good light in the public eye, has been long in operation. Dr. Hess said, "A public relations program, as I see it, is a concentrated effort to do good and to gain public recognition of such deeds. In too many instances the inverse attitude is maintained. A drum-beating campaign is established to create the impression of altruistic purpose with no sincere desire to back up fine words with suitable deeds."

Dr. Hess warned that in trying to bring the profession into a more favorable light, the profession may have neglected to do some soul-searching on its own. He asked, "Is it possible that we spend too much time telling each other what great humanitarians we are while the pot of lay discontent is boiling over in the next room?"

He urged physicians to reconsider a rededication to the firm basis of the profession itself: service. "So far as I'm concerned the most important rule that physicians should follow is that we *must* care for the sick and infirm, regardless of fees, salaries or honorariums," he declared. "The backbone of medical ethics is summed up in a short sentence: 'Service to suffering humanity, period.'"

His concluding remarks were: "Words alone are not sufficient to convince a cynical public of the humanitarian purposes of medicine. Let us not just try to **convince** the public; let us DO for the public."

REPORT SHOWS UNITED STATES COST OF SICKNESS

Some favorable information on doctors' fees in relation to the cost of sickness in the United States, is shown in a recent special article in *U. S. News & World Report* magazine. Quoted in the AMA Secretary's Letter, the article states: "Government experts attribute most of the rise in hospital expense to higher charges resulting from better pay scales for hospital workers and the higher cost of food."

Doctors' Fees Less

"Dentists and physicians, on the other hand," the article goes on, "are getting a somewhat smaller share of the nation's private medical outlays. This finding runs counter to criticism of physicians' fees." Further explanation is made:

> "Physicians' fees used to account for 30 per cent of the out-of-pocket cost; now they are 29 per cent. Dental bills are less than 10 per cent today, compared with more than 12 per cent in 1948. These fees tend to stay fairly constant for periods of years. The last big jump came during World War II. Today many physicians are charging the same for office calls and sickroom visits as they did shortly after the war."

The report stated that medical care is costing people a total of 12.4 billion dollars a year, of which 2.1 billion is met through health insurance.

Almost 400,000 nurses now are on active duty in the United States, an increase of 16,000 in five years, according to a Public Health Service survey. The estimate shows the following: 231,000 hospital nurses, a 15 per cent increase in four years; 74,000 private duty nurses; 35,200 nurses working in physicians' offices; 25,300 public health nurses; 14,000 industrial nurses; 8,200 nurse educators and 1,900 in a variety of other fields. Although the ratio of nursing personnel to patients is at an all-time peak, 74 per 100, Surgeon General Scheele said the need for nurses justified the present annual student nurse recruitment goal of 55,000.

CLINICAL-PATHOLOGICAL CONFERENCE

(Continued from Page 116)

normalities. The right lung weighed 730 grams, the left 510 grams. Moderate pulmonary edema and patchy bronchopneumonia were evident. The liver weighed 2480 grams, showed only engorgement of the central sinusoids microscopically; no evidence of hepatitis, cirrhosis or fatty metamorphosis could be found. The spleen weighed 210 grams, was not abnormal grossly or microscopically. The gastrointestinal system and pancreas were not abnormal. The right kidney weighed 150 grams, the left 225 grams; they showed no gross or microscopic pathology and the ureters were not dilated. A suprapubic cystotomy opening was still patent and the urinary bladder mucosa very hemorrhagic. The prostate was enlarged considerably, measuring 7 by 6 by 6 cm., remarkably firm, homogeneous and gray-white. The microscopic appearance was that of a characteristic well-differentiated adenocarcinoma. The adrenal glands were not abnormal grossly or microscopically. Many periaortic and supraclavicular lymph nodes showed metastatic carcinoma. The sternum and lumbar vertebrae showed metastatic carcinoma to such a degree that only an occasional focus of uninvolved marrow could be found on microscopic examination.

In view of the clinical course and laboratory findings, it was our opinion that the hemorrhagic diathesis could not be explained on the basis of bone marrow replacement by metastatic tumor alone, and that the fibrinolysin system, as pointed out by Dr. Goldish, was probably the major factor in the bleeding process.

Dr. John Wolff (Duluth Clinic): I agree that this patient had a thrombocytopenia, probably myelophthisic, and circulating fibrinolysin in significant amounts; I doubt whether they are related to each other. The apparent paradox of failure to clot with addition of thrombin but an almost normal plasma fibrinogen may be resolved by the concept of antifibrinolysin in normal plasma. The possibility of acute adrenal insufficiency as immediate cause of death must be kept in mind because of the relatively rapid withdrawal of ACTH.

Public Health

GUIDE FOR MEDICAL POLICIES FOR LOCAL PUBLIC HEALTH NURSING SERVICES

These medical policies have been jointly agreed upon by the Public Health Nursing Committee of the Minnesota State Medical Association and the Section of Public Health Nursing, Minnesota Department of Health.

Preamble

A public health nursing program for any community includes:

1. Part-time home nursing care and rehabilitation nursing for the sick and disabled.
2. Health guidance for families.
3. Participation in community measures to prevent disease.

In addition to part-time home nursing care service, the public health nurse offers health guidance to the entire family. She serves families through the home, school, at work and in clinics. She has contacts with many persons who are not ill but who might benefit by health instruction and health guidance.

Public health nursing services should be available to everyone in the community—rich or poor and without regard to race, color or creed. Bedside nursing care services should be provided on a fee basis in accordance with the individual's ability to pay.

Another principle of a sound public health nursing organization is that every local public health nursing service appoint a medical advisory committee. A public health nursing service can function successfully only in close co-operation with the medical profession.

Representation on the medical advisory committee of the local public health nursing service should include the local medical society, medical specialty groups, and the health officer. In areas where there are few physicians, all of them may be members of the committee.

The chairman of the medical advisory committee should be a member of the administering body (the board) of the local public health nursing agency. Written medical policies for the agency should be prepared and signed by the members of the medical advisory committee.

Functions of the Medical Advisory Committee

1. To discuss and recommend medical policies to be followed by the nursing staff.
2. To make recommendations to the Board regarding the initiation and continuance of special phases of the agency's program that involve medical consideration.
3. To help prepare or to approve any publicity that involves medical information or that is to be sent to physicians; and to help with the selection of medical speakers for annual and public meetings.
4. To act as liaison between the public health nursing service and the medical society.
5. To interpret the organization to the medical society.
6. To approve the content and frequency of health examinations of the staff before and during employment and to advise regarding a health program for the staff.

Suggested Medical Policies

Except under highly unusual circumstances, public health nurses should not be expected to answer to the directions of persons other than licensed physicians and surgeons. Provided, however, that public health nurses may carry out nursing functions under the direction of other licensed health practitioners insofar as the practices of the latter, in medical and surgical fields, are within the limits of their licensure, and insofar as such orders may be compatible with the training and experience of public health nurses to perform.

The public health nurse rendering bedside nursing care and rehabilitation nursing services to acute or chronically ill persons at home, shall obtain verbal or written orders directly from the physician. Chronically ill patients shall be seen by a physician not less often than every six months if nursing service is to be continued.

Written orders for any treatment or for hypodermic therapy must be obtained from the physician.

Records of nursing services to individuals or families are kept in a confidential file in the office of the local public health nursing agency. The nurse should make a written report to the referring physician and/or agency of the services she has rendered to the family.

Approved by the Minnesota State Medical Association, December 12, 1954.

Hypodermic Policy.—Nurses are permitted to give intradermal, subcutaneous and intramuscular injections on written orders from the physician. Orders should include the name of the drug, dosage, frequency and method of administration and any precautions necessary The nurse may accept verbal orders if arrangements are made to have them in writing by the next day. The administration of one dose of insulin upon direct verbal order of the physician is included in this policy. Families may be instructed to give intramuscular injection on written request of the physician.

The nurse may *not* give intravenous injections, cold shots, or drugs which may commonly cause severe reactions. The Medical Advisory Committee will be consulted about the requests for any questionable or unfamiliar therapy.

At such times as the services of licensed practical nurses, nurses aides or homemaker services are indicated, the public health nurse will plan accordingly with the family and the family physician. However, the public health nurse will continue to assist the worker and the family on the basis of need. The public health nurse, after consultation and in co-operation with the family physician, may refer patients to the local public and private health and welfare facilities.

The establishment of clinics or other health activities which involve medical service shall be undertaken only upon approval of the local physicians in the community or county or District Medical Society.

Suggested Standing Orders

(Until nurse can contact physician)

The following orders are used only until the nurse can get in touch with the physician. No more than two visits shall be made to an ill patient who is not under the care of a physician. If there is no physician, the family is urged to select and call one and an explanation is made that the nurse cannot continue care except under the physician's directions.

1. New Patient: Bathe and make patient comfortable. Instruct family as to care.
2. Burns: Apply sterile dressings to superficial burns. If burns are severe, advise and help arrange immediate medical care. If transportation of the patient is indicated, extensive burns may be covered with a sheet. Avoid use of ointments.
3. Surgical Dressings: Dressings may be reinforced.
4. Minor abrasions and cuts: Wash with soap and water and cover with clean dressing.
5. Varicose Ulcers: Cleanse; apply sterile dressing and bandage firmly.
6. Sore Throats and Colds: Isolate, urge fluids.
7. Suspected communicable diseases: Isolate and give nursing care and instruction as indicated. If family refuses to call physician, notify local health officer.
8. Discharging Ears: Clean outer ear with swabs moistened with boiled water. Dry thoroughly. Do not irrigate. Urge prompt medical attention.
9. Accidents: The nurse will limit herself to those accepted procedures described in the American Red Cross First Aid Handbook. Medical care should be arranged for immediately.

Suggestions About Program

Health of Mothers.—The public health nurse's work with mothers and infants is an important part of public health service.

In working with expectant mothers the aim is to bring the women under early and continuous medical care and to teach the elements of prenatal hygiene and good nutrition practices. The public health nurse should secure orders from the individual physicians for treatment and nursing procedures to be carried out for their patients. Prenatal classes for patients are highly encouraged. They should be organized under the auspices or with the approval and active support of the local physicians.

It is most important that the mothers be instructed to return to their physicians for their postpartum medical check-up.

Encouragement is given to mothers to breast feed their infants except where contraindicated. Instruction is given in the care of the breasts and the proper techniques for breast feeding.

Health of Infants and Preschool Children.—Every effort should be made to contact the mother of a new infant within 48 hours after the infant's discharge from the hospital. In the case of the prematurely born infant the mother should preferably be contacted before she leaves the hospital and plans should be made for preparing the home for the prematurely born infant and for subsequent visits to the home with the approval of the attending physician.

The value of continuous health supervision and appropriate medical services for the infant and preschool child by the private physician or clinic should be stressed. This health supervision includes determination of the health status of the child and deviations from normal; immunization against such diseases as diphtheria, pertussis smallpox and tetanus; and counseling in all phases of infant and child care and growth and development. The public health nurse supplements the instruction given by the physician and elaborates on the details, especially as concerns techniques of food preparation and feeding, daily care of the infant, good hygiene practices, habit training accident prevention, et cetera.

Health of School Children.—School health work may operate under the immediate direction of the school administrator. The "School Health Manual for use in Minnesota Schools" should constitute the base line upon which programs for the health of school children are constructed. In addition, the nursing board and the school health council (if there is one), each with medical, dental and lay representation, should help guide the service. The nurse consults with parents on problems of child health and environment and guides parents to other sources of aid which may be needed. The nurse co-operates with the school staff, parents, physicians and dentists in arranging for and conducting health programs in such a manner that they become an educational experience for all participants.

The school nurse aids in the control of communicable disease by helping parents and teachers recognize conditions for which the child should be isolated. Primary responsibility for exclusion of sick children is fixed by Minnesota State Board of Health Regulation number 318 which reads:

> "The person in charge of a school shall exclude from school all children who (a) return to school after an illness of unknown cause, (b) appear to be in ill health, (c) have lice or other vermin. The parents of such children shall be notified of the reason for exclusion and such cases shall be referred to the family physician, the school physician or the health officer. Children shall not be readmitted until they obtain a certificate from the health officer or his authorized agent."

Crippled Children Services.—The State Service for Crippled Children merits full co-operation of all interested local agencies to fulfill its functions. The prevention and correction of physical handicaps due to bodily defects needs supervision over long periods of time. The nurse works with the individual physician in the care and supervision of these cases.

Due to her close contact with the patient, the public health nurse may discover deviations from the normal—not only in the infant, but also in the preschool and school child. She helps parents make precise and concrete plans for the regular and continuing medical care of the crippled child.

The nurse's duties in the individual case lie in the education of the family in the patient's care, the demonstration of and instruction in home nursing, the general health supervision of the afflicted child, and the supervision of therapeutic exercises recommended by the physician in charge. The nurse will aid the rehabilitation of the patient in every way.

Communicable Disease Control.—The control of communicable diseases is the responsibility, not only of the public health nurse and the official agency, but is also the concern of the medical profession and general populace. If communicable disease is suspected, the nurse should explain to the family the elementary principles of isolation, concurrent and terminal disinfection and such other measures which will aid in preventing the spread of disease.

In aiding physicians in the control of preventable diseases, public health nurses are expected to co-operate with the local health officer and to follow the Regulations of the State Board of Health.

The nurse should teach families that immunizations for infants should be started at 3 or 4 months of age and thereafter repeated at regular intervals as determined by the physician. Group immunization programs should be conducted under the auspices or with the approval of a local medical society. (A number of biological preparations for mass immunization programs are available without cost upon application to the Minnesota Department of Health.) The nurse's contribution to such programs consists of participation in preliminary education of the community, assisting with the necessary arrangements for carrying through the programs, assisting the physicians when the immunizations are being performed, summarizing reports, and keeping local records of immunization.

Tuberculosis Control.—The public health nurse contributes to the control program through her work with the family. She is often able to bring a suspected case of tuberculosis to the attention of the physician, thereby assuring an early diagnosis. She teaches the need for participating in tuberculin testing programs and in mass x-ray surveys.

Her service to the family includes sharing information about the disease; nursing care services to patient in the home; taking steps to prevent the spread of tuberculosis and helping the patient and family make necessary adjustments.

Rehabilitation and the return of the patient to his community and his family needs skillful guidance and arrangement of an environment in which the patient can carry on the recommended treatment.

If drug therapy is to be given a patient by the nurse, she should first secure from the supervising physician specific written instructions for her guidance; from time to time these instructions should be changed to fit changes in the prescribed treatment.

Minnesota Academy of Medicine

Meeting of March 10, 1954

The regular monthly meeting of the Minnesota Academy of Medicine was held at the Town and Country Club on Wednesday evening, March 10, 1954. Dinner was served at 7 p.m. and the meeting was called to order at 8:20 p.m. by the vice-president, Dr. C. N. Hensel.

There were forty-eight members and one guest present.

Minutes of the February meeting were not read due to the length of the scientific program.

The following memorial was presented at this meeting.

Arthur Edwin Benjamin

1868 - 1953

Dr. Arthur Edwin Benjamin, a member of this Academy since 1903, died October 1, 1953, after an active practice in Minneapolis covering a span of over sixty years. He was born in Hutchinson, Minnesota, in 1868. His father and grandfather were physicians.

Dr. Benjamin received his degree in medicine from the University of Minnesota in 1892. Even before graduation, his teaching ability was recognized and in 1890 he was made an assistant instructor in gynecology. After graduation, he continued in the department of gynecology and, after postgraduate study in London, Vienna and New York, was made chief of one of the gynecological services at the Minneapolis General Hospital. He served in this capacity until his retirement as professor emeritus in 1938. He continued on the service as consultant. By those of us who served under him during those years, his conscientious care of the patients, the excellent results of his diagnostic acumen, surgical judgment and operative skill, and his constant kindly and helpful consideration of his staff will long be remembered.

Dr. Benjamin was very active in the Hennepin County Medical Society and became one of its presidents. He was always most conscientious in the performance of any assignment given to him during his long association with that Society. Other medical society memberships included the Minnesota State Medical Association, the American Medical Association, the American College of Surgeons, the Western Surgical Society and the Southern Minnesota Medical Association. He belonged to the staffs of St. Barnabas and Northwestern Hospitals, and was once chief of staff of the latter.

Dr. Benjamin, though singularly quiet, retiring and unassuming, was a man of tremendous energy and wide interests, social, political, religious and artistic. His affiliations with organizations devoted to these fields have been amply memorialized in the public press and scientific journals.

In the course of his membership in this Academy, he was always very modest, never presenting or discussing any paper unless he felt strongly that his opinion, founded upon sound study and a wide personal experience, would be of value. As those acquainted with his writings well know, he devised many clever techniques and operations.

In our social hours, we shall miss his friendly presence and his studied comments on any one of a wide range of important subjects in which he was interested. Especially shall we miss his observations upon the changes that took place during the long span of his practice, observations spiced with humor and always kindly.

Dr. Benjamin is survived by two sons, Edwin G. and Harold G. Benjamin, who are carrying on the family tradition of medicine and are practicing in Minneapolis; two daughters, Mrs. Charles J. Hoover of St. Louis Park, and Alice, who is the principal of Summit School, Saint Paul; a sister, Mrs. Olive Bacon of San Gabriel, California; a brother, Dr. Winifred G. Benjamin, a dentist in Minneapolis; and seven grandchildren.

R. T. La Vake, M.D.

The secretary announced the Executive Committee had approved the transfer of Dr. A. G. Schulze to the Senior list. Upon motion, this was seconded and carried.

The scientific program followed.

Dr. C. A. McKinlay, of Minneapolis, read his inaugural thesis on "Clinical Observations Related to Pulmonary Eosinophilia." Lantern slides were shown.

CLINICAL OBSERVATIONS RELATED TO PULMONARY EOSINOPHILIA

C. A. McKINLAY, M.D.
Minneapolis, Minnesota

This paper presents two cases of eosinophilic pulmonary infiltration, both of them transient and recurrent, in which observations were made during illness and subsequent health over a period of twenty patient-years.

Personal interest in eosinophilic pulmonary infiltration had followed observation in 1939 and report in 1941 by Ellis and myself[9] of a case of pneumonia (S. L., a twenty-two-year-old white man) with massive migratory pulmonary infiltration associated with high (48 per cent) blood eosinophilia. Prompt clinical recovery followed discontinuance of prontosil, which had been given on another service for the treatment of colitis. At no time had there been marked prostration. Our attention was called to the report by Löffler,[14] in 1932, of fleeting pulmonary infiltration with eosinophilia. Other reports from Europe followed soon. The importance of the lung as a shock organ had long been recognized, and true bronchial asthma was universally accepted as a manifestation of hypersensitiveness. However, extensive pneumonitis as an allergic response to agents other than infection was a relatively new concept; in fact, no cases occurring in the United States were then found reported. The next case I wish to cite is one that had been observed by the late Dr. P. Hallock and by Dr. W. W. Spink in 1941, and by the writer since 1949.

Case Reports

Case 1.—H. F., a white man aged forty-six, a contractor, was admitted to the hospital March 24, 1949, because of a respiratory infection of two weeks' duration associated with moderate malaise.

Past History.—The hospital record of 1941 was reviewed. At that time, the patient had been observed in the hospital with atypical pneumonia and had been discharged as recovered. Following readmission to another hospital one week later, tachycardia and bouts of fever were noted. There were areas of infiltration in both lungs. The leukocyte count varied from 8,100 to 15,200 with maximal eosinophilia of 27 per cent. There were occasional eosinophils in the sputum. The electrocardiogram was abnormal, with a negative T_2. Toxic myocardium was suggested. Dr. Spink suggested Löffler's syndrome. Omission of sulfadiazine was suggested. Potassium iodide gr. XV daily appeared beneficial on repeated trials. The patient was afebrile when discharged.

Physical Examination.—On March 24, 1949, there were râles, chiefly at the left base. The chest x-rays showed multiple extensive areas of infiltration in both lungs. The leukocyte count varied from 8,100 to 18,900, with eosinophils of 6 to 21 per cent. The sedimentation rate was 96 mm. per hour; heterophile agglutinins were present in a titer of 1:20. The sputum showed no predominating organisms. The urinalysis gave negative findings. Skin tests using multiple allergens from various sources were negative. Muscle biopsy findings excluded periarteritis nodosa in one specimen. The maximal temperature was 102° F.; usually it was below 101° F. There was depression of the temperature for three days following the use of potassium iodide gr. V, but fever recurred. Potassium iodide gr. X was resumed April 18 and continued until discharge on April 30, with associated relief from fever on most of the days.

The patient was next admitted to the hospital on June 16, 1949, one week after having had an attack of biliary colic with associated jaundice and clay-colored stools for two days. During hospitalization, the patient improved, was afebrile, and the eosinophils dropped to 7 per cent. Eleven days later, during readmission to the hospital and after the jaundice had subsided, fever. leukocytosis and eosinophilia reappeared. While jaundice was present, there was amelioration of the pulmonary eosinophilia. At the present time the patient is well, thirteen years after his first attack, the x-ray shows no evidence of infiltration, and the blood count remains normal.

Case 2.—Mrs. C. B., a farm housewife aged thirty-five and mother of five children, was first examined on April [illegible], 1948, with the complaint of fatigue. About six months previously, the patient had an acute respiratory infection with systemic reaction for which she was hospitalized for two weeks. X-ray examination elsewhere suggested pulmonary tuberculosis to the radiologist. For ten days, she received penicillin and, for four days, a small amount of a sulfonamide. During this period, asthma developed. This subsided after a brief interval, but ever, malaise and persistent cough continued and she equired almost constant rest in bed. Scratch tests with penicillin were negative.

The laboratory findings at variance from normal were: emoglobin 11.3 gm., leukocytes 11,100 and 39 per cent osinophilia. At another time 45 per cent eosinophilia was noted; the sedimentation rate was 114 mm. per hour. Negative findings of importance were: absence of ova nd parasites, normal serum protein, normal heterophile eaction, negative blood culture, absence of acid-fast acteria and negative bone-marrow except for marked eosinophilia. The treatment was symptomatic; the temperature was only slightly elevated on three of eleven hospital days.

After three years of good health, the patient was next observed on March 18, 1953, with fever, fatigue and dyspnea of six weeks' duration. There were minimal physical findings in the chest. X-ray examination showed extensive infiltration in both lung fields. The routine laboratory findings were: hemoglobin 11.7 gm., leukocyte count 11,800 and 20,600, with 38 to 48 per cent eosinophils; sedimentation rate 112 mm. per hour; sputum showed mixed growth. Clinical improvement occurred, and the patient was discharged. She was readmitted about two months later because of recurrent bouts of respiratory symptoms, fever and fatigue. Liver function tests were normal. Moderate fever subsided during ten days' hospitalization. The patient was readmitted July 13, 1953, because of recurrence of fever, fatigue and cough. The hemoglobin was now 10.1 gm.; the leukocytes were 14,000, with 36 per cent eosinophils. Cortisone was started orally and given daily in the maximal amount of 200 mg. There was immediate clinical improvement. On the third day of treatment, with a leukocyte count of 12,400, the eosinophils numbered 1 per cent; on the following days the eosinophils were 0, 1, 3, 1 and 10 per cent. This response is in keeping with the known influence of cortisone in lowering blood eosinophilia in persons with intact adrenals. She is now on a small maintenance dose of cortisone and is in excellent health, according to Dr. R. F. Gammell, through whose courtesy the patient was examined. Rose[6] first reported benefit in a case of Löffler's syndrome following the use of cortisone.

Other Cases

C. T., a man aged twenty-four, currently being observed, is cited with an upper respiratory tract infection associated with eosinophilia (32 per cent). This case illustrates that various infections and infestations provoke eosinophilic blood response without causing pulmonary infiltrations.

The high degree of eosinophilia (53 and 44 per cent) noted in asthmatic bronchitis without pulmonary infiltration and in intestinal parasitism is illustrated by the case of V. S., a man aged twenty-three, a native of India, recently observed. It has been suggested that eosinophils develop as a result of destruction of body tissue. The dissimilarity of pulmonary eosinophilia to eosinophilic granuloma of the lung should be noted. Histamine may be contained in the eosinophils of the blood.

Blood eosinophilia is an incidental finding in certain pulmonary conditions, such as sarcoidosis, hydatid disease of the lung, Hodgkin's disease and the resolving stage of pneumonia. Since 1941, there has been reported an increasing number of cases in which pulmonary infiltrations have been observed radiologically and which have been accompanied by blood eosinophilia. The term "Löffler's syndrome"[9] has included only a part of this group of diseases and should be limited to those cases with transient pulmonary infiltration and eosinophilia. There is a growing tendency to link Löffler's syndrome, erythema nodosum and tropical eosinophilia, in which there may or may not be infiltrations, under an inclusive term. Crofton and associates,[6] in their review in 1952 of some 450 cases reported in the literature, suggested the term "pulmonary eosinophilia." Under this term, they suggested the classification of (1) simple pulmonary infiltration or Löffler's syndrome, transient infiltrations; (2) prolonged eosinophilia, prolonged or recurrent infiltrations without asthma; (3) pulmonary eosinophilia with asthma, infiltrations with asthma; (4) tropical pulmonary eosinophilia usually with asthmatic symptoms; (5) polyarteritis nodosa.

Löffler's syndrome in the continental cases reported has commonly been associated with infestation by Ascaris lumbricoides. The complete syndrome was reproduced by Vogel and Minning[21] in five of six volunteers by feeding Ascaris eggs. Other worms have been incriminated, such as Ancylostoma braziliense causing creeping eruption or itch reported by Wright and Gold,[22] Taenia saginata by Benda and Weinberg[2] and hydatid of the liver by Dörig.[8] Among miscellaneous allergens are pollens, such as privet,[10] beeswax,[11] and sulfonamides.[5] Cases with significant agglutinin titers for Brucella abortus were found. There were two with Strongyloides stercoralis infestation,[4] and one with microfilariae in the sputum. This syndrome has also followed penicillin therapy.[17]

Tropical eosinophilia, or tropical pulmonary eosinophilia, has been reviewed by Danaraj[7] and may represent another variant. In a report of 150 cases in the Orient, 81 per cent had pulmonary infiltration that showed by x-ray. This disease often has an initial febrile stage with respiratory symptoms followed by bronchitis, which becomes the most prominent feature and which may last for months or years. There is an asthmatic stage which may likewise last for months. The most dramatic aspect is the response to organic arsenic administered orally or intravenously. The cause is not yet known. Danaraj[7] rejected the theory of hypersensitivity.

Pulmonary eosinophilia may occur with asthma. Harkavy,[13] in 1943, described fifteen cases of asthma associated with recurrent pulmonary infiltration and eosinophilia. In fatal cases, in addition to edema and cellular exudate, there were lesions in the blood vessels, including acute necrotizing arteritis. This observer[13] noted widespread tissue involvement. A transient eosinophilic gastric lesion has been described.[20] Bayley and co-workers[1] reported a fatal case of Löffler's syndrome in which the outstanding pathologic findings were the large number of eosinophils in the pneumonic exudate, granulomatous lesions and necrotizing arteritis. Bergstrand[3] described similar and widespread findings of polyarteritis nodosa in four asthmatic persons who had transient pulmonary infiltrations and eosinophilia. The pathological variation from simple pulmonary eosinophilia, or Löffler's syndrome, to the widespread necrotic arteriolar changes of polyarteritis nodosa somewhat parallels the range of clinical manifestations from simple pulmonary eosinophilia. Crofton's group[6] argued that the variants described are different grades of the same fundamental process. The diversity of causative agents, the eosinophilia, and frequently the family history of allergic illness, suggest that the process is one of hypersensitivity. Rich[18] has shown that polyarteritis nodosa is a reaction of hypersensitivity. Some allergens such as those that might be implicated in tropical eosinophilia appear to be powerful enough to produce the reaction in most people. Reeder and Goodrich[16] reported, among others, a fatal case in which progressive periarteritis nodosa accompanied the "PIE-syndrome"; this latter term was suggested by these authors for pulmonary infiltration with eosinophilia. Mark[15] recently reported twenty-three cases of Löffler's syndrome and considered that the role of allergies is minor in the development of pulmonary change.

Summary

Cases herein reported include an interesting experiment by nature in which the fortuitous occurrence of jaundice benefited a patient who had recurrent pulmonary eosinophilia in a manner similar to that of the influence of jaundice upon rheumatoid disease, first stressed by Hench.[13] Another patient received benefit from the use of cortisone, which linked this case physiologically to the case in which benefit was derived from jaundice. Because of their relatively benign nature, these cases, with recovery after repeated transient pulmonary infiltrations, contrast with the irreversible stage of periarteritis nodosa which sometimes supervenes in the syndrome of pulmonary eosinophilia.

Discussion

Dr. Leo G. Rigler, University of Minnesota: It is interesting to me to hear Dr. McKinlay mention tropical eosinophilia. When I was in India, I heard Dr. Sanjivi report on a large number of such cases. They differed somewhat from the typical Löffler syndrome which Dr. McKinlay has discussed in detail. In India, tropical eosinophilia lasts for a long time and the condition has been concentrated in children and young adults. It simulates miliary tuberculosis very closely in the roentgenogram. Since miliary tuberculosis is extremely common in India, my first impression on seeing such cases was tuberculosis, but the clinical picture is not at all like miliary tuberculosis. The eosinophilia is commonly as high as 60 to 70 per cent. Dr. Sanjivi studied the cases intensively but did not succeed in determining the etiological factor; so far as I could determine, he was completely mystified as to the cause.

Dr. F. W. Lynch, Saint Paul: As Dr. McKinlay has pointed out, the problem of eosinophilic infiltration interests practitioners in many fields of medicine. Observations in the dermatologic field may be of interest to others because we can more easily perform biopsies and thoroughly study the lesions which we see. Eosinophilic leukemia is rare and even when present it is very rarely accompanied by specific cutaneous manifestations and therefore this problem does not deserve our consideration tonight.

Eosinophilic infiltration often accompanies allergic dermatoses but this too is beyond the range of tonight's discussion. We also see fixed granulomatous circumscribed lesions, chiefly on the face, persisting for months or several years and not easily influenced by treatment. They have been of particular interest because one would suspect they would be accompanied by some systemic manifestations, though this has proved not to be the case. Perhaps they are comparable with fixed eosinophilic infiltrations in other tissues, as in the bone or the lung. However, many or most of the osseous lesions seem more closely allied with Hand-Schüller-Christian disease and therefore have much more serious implications than do the fixed circumscribed lesions. To the dermatologist it seems difficult to link all these varied eosinophilic infiltrations and we regard them as separate entities. They have in common only the presence of large numbers of eosinophils. Changes in white blood cell counts do not parallel the cutaneous nor the osseous findings.

Dr. E. P. K. Fenger, Oak Terrace: I enjoyed Dr. McKinlay's paper very much. Dr. Rigler has made the statement that pulmonary eosinophilia may be mistakenly diagnosed as tuberculosis. I find that at Glen Lake Sanatorium, during the past fifteen years, we have had seven such cases admitted. These seven cases fit into Dr. J. W. Crofton's classification very well. There were two in the simple eosinophilia group, three in the prolonged pulmonary eosinophilia group, and two in the group of pulmonary eosinophilia with asthma. I think there are two other clinical entities that should be mentioned; one is eosinophilic pleural effusion and the other is eosinophilic granuloma of the lung.

Dr McKinlay, in closing: I wish to thank the members very much for their discussions. It may be of interest to mention that patient H. F., while on a trip in the Caribbean area in 1951, had recurrence of eosinophilic pulmonary infiltration. The patient was advised by local physicians of the relative frequency of occurrence of the disease in the neighboring tropical communities.

* * *

Dr. Lyle J. Hay, Minneapolis Veterans Hospital, Department of Surgery, gave his inaugural thesis on "Transplantation of the Duct of Wirsung in the Treatment of Chronic Pancreatitis." Case reports were given and lantern slides were shown. (Thesis to be published later)

Discussion

Dr. A. A. Zierold, Minneapolis: It has been very interesting to listen to Dr. Hay's recapitulation of the theory of the common pathway of the biliary and pancreatic ducts. Those of us who are accustomed to employ operating-room cholangiograms have found this to be demonstrable in a surprisingly large percentage of cases. Considering acute pancreatitis, there can be little question as to its identity, but I believe that what we are accustomed to call recurrent subacute or relapsing pancreatitis may quite as well be a symptom complex arising from the reflux of the pancreatic secretion into the biliary tract. Whatever the case may be, Dr. Hay has demonstrated that symptoms arising out of the common pathway may be obviated by transplantation of the pancreatic duct. It is probable that the only other choice of treatment is section of the sphincter of Oddi.

It is gratifying to hear Dr. Hay's experience and I shall be interested in a comparison of the two procedures after more cases have been accumulated and further time has elapsed.

The meeting was adjourned.

Robert E. Priest, M.D., *Secretary*

In Memoriam

LYLE V. BERGHS

Dr. Lyle V. Berghs, native son of Owatonna, died in Albert Lea on December 4, 1954, of coronary thrombosis. Dr. Berghs was on his way to Kiester where he was to have re-entered private practice with another physician. He was forty-eight.

Dr. Berghs' death followed several years marked by extensive periods of hospitalization and surgery in an attempt to correct his circulatory condition.

Dr. Berghs was the first volunteer to answer the Steele county medical draft during World War II. He served thirty-seven months of intensive service, with twenty-two months overseas, in England and in North Ireland. As ship surgeon, he was wounded in a strafing attack before D-Day and was hospitalized in England, but he recovered enough to join the combat and attack forces on D-Day and served with his medical unit at the front lines through the heaviest drives.

He was born in Owatonna on April 20, 1906, and attended grade and high school there. He entered the University of Minnesota and graduated from medical school in 1929, interning at Minneapolis General Hospital. In 1930, he began his practice in Owatonna with Dr. D. H. Dewey, and renewed the practice after his service during World War II. In 1952, he was appointed to the staff of Moose Lake Hospital and served for two years.

He had been a member of the Steele County Medical Society, the Minnesota State Medical Association and the American Medical Association, the American Legion, the Veterans of Foreign Wars, Alpha Omega Alpha, the BPOE and the Holy Name Society.

He is survived by his wife, the former Adele Whetstone; one son, Thomas, Winona; one daughter, Peggy, Minneapolis; two brothers, Charles, Park Ridge, Illinois; Larry, Owatonna; two sisters, Mrs. Max Argent, Hampton, Iowa, and Mrs. Warren Gray, Waseca.

KARL EMIL BERGQUIST

Dr. Karl E. Bergquist, Battle Lake, died at Lake Region Hospital on December 10, 1954. Dr. Bergquist, well-known and loved resident of Battle Lake, would have been eighty years old on Christmas eve. He was born in St. Peter.

Dr. Bergquist came to Battle Lake from Duluth in 1935, and specialized in eye, ear, nose and throat work. He was appointed resident physician for the Otter Tail County Sanatorium in December, 1943 and served in that capacity until October, 1954.

Dr. Bergquist received his medical education at the University of Minnesota and at Hamline University, graduating in 1897. He interned at Bethesda Hospital in Saint Paul, and did postgraduate work in Chicago in his specialty.

He was married to Borghild Torkelson of Minneapolis in 1902. Mrs. Bergquist preceded him in death in 1945.

Dr. Bergquist was a life-time member of the Trinity Lutheran Church in Duluth; the Vasa Ama Society, the Park Region District and County Medical Society, the Minnesota State Medical Association and the American Medical Association.

Surviving are two daughters: Mrs. Ethel Campbell, South Bend, Indiana; Mrs. C. A. Boline, Battle Lake; four grandsons: John Lloyd Campbell, U. S. Navy; Karl Allan, Jon Edward and Robert A. Boline, Battle Lake; three brothers: Theodore, Lafayette; Oscar, Galesville, Wisconsin; and Ernest, Rapid City, South Dakota.

ROBERT ALLEN CAMPBELL

Dr. Robert A. Campbell, retired Minneapolis physician and surgeon, died on January 7, 1955. He was eighty-six.

Dr. Campbell was an eye, ear, nose and throat specialist who practiced in Minneapolis more than fifty years. He was born in Detroit on December 27, 1868, and graduated from the University of Minnesota Medical School in 1896 and was licensed in the same year.

Dr. Campbell was a member of Phi Gamma Delta and Nu Sigma Nu, medical fraternities; a former member of the Hennepin County Medical Society, the Minnesota State Medical Association and the American Medical Association. He was a fellow of the American College of Surgeons and was for many years on the staff of Abbott Hospital.

He is survived by his wife, Mary S.; one daughter, Dorothy; one son, Gilbert M., Sacramento, California; one brother, George G., Portland, Oregon; two sisters, Mrs. Mert Patterson, Portland, Oregon and Mrs. William Cowing, Hamilton, Canada.

ROBERT WILSON CAMPBELL

Dr. Robert W. Campbell, prominent Cass Lake physician for many years, died at Rochester, December 13, 1954. He was seventy-five.

Dr. Campbell was born at Parkers Lake in Hennepin County, on February 14, 1879. He obtained his preliminary education at Tracy and received his medical education at the University of Minnesota, from which he graduated in 1905. He set up his practice in Swanville in 1905, moving to Deering, North Dakota, in 1914 and remaining there until 1919. From 1919 to 1926 he practiced in Blackduck, Minnesota, and then moved to Bisbee, North Dakota, until 1930 when he located at Cass Lake, where he remained until his death.

After his graduation, he took one year's internship at City and County Hospital in Stillwater and did postgraduate work in Chicago for six months.

Dr. Campbell founded the Cass Lake General Hospital. He was chairman of the Civic Improvement Committee of Cass Lake, and as such he drew the first plans for the community's lakeshore park. He also belonged to many civic and fraternal organizations.

He retired from active practice about ten years ago. He has been a member of the Upper Mississippi Medical Society, the Minnesota State Medical Association and the American Medical Association.

Dr. Campbell is survived by his wife; a son, Robert, Rochester; and three daughters, Mrs. A. B. North and Mrs. Glenn Harris, both of Los Angeles, and Audrey, believed to be in Minneapolis.

ENOCH HAUGSETH

Dr. Enoch Haugseth, retired Twin Valley physician, died at his home at the age of eighty-three on December 2, 1954.

Dr. Haugseth had been in retirement for about fourteen years at the time of his death, but had been in Twin Valley since 1906, practicing actively for about twenty-five years.

Dr. Haughseth was born on September 21, 1871, in Rendalen, Norway. He became a citizen of the United States in 1896, two years after he graduated as a pharmacist from the University of Minnesota. In 1902, he received his M.D. degree.

After practicing at Lake Park from 1902 to 1906, Dr. Haugseth came to Twin Valley. He was much interested in local church activities and also served for a number of years as president of the local school board, and as local health officer. He was also local surgeon for the Northern Pacific Railway.

Dr. Haugseth had been a member of the Red River Valley Medical Society and the Minnesota State Medical Association.

He is survived by his wife, the former Elizabeth Wold; three daughters, Mrs. Walter Johnson, Twin Valley; Mrs. Arthur Tillinghast, Great Neck, New York; and Mrs. Ralph Fjelstad, Northfield; two sons, Dr. Ellsworth, South Bend, Indiana, and Enoch of Seattle; and fourteen grandchildren. One son, Clarence, Portland, North Dakota, preceded him in death.

GUSTAV M. HELLAND

Dr. Gustav Helland of Spring Grove died at his home after a long illness, on December 8, 1954. He would have been seventy-nine on December 23. He was one of Spring Grove's early physicians, arriving in 1910 and serving until 1945 when ill health forced him to retire.

Dr. Helland was born in Lisbon, Illinois, in 1875. He lived on a farm near Black Earth, Wisconsin, as a child and attended grade and high school there. From 1892 to 1898, he worked as a pharmacist in Chicago; later he owned and operated a drug store in Mount Horeb, Wisconsin. Entering medical school, he received his medical degree from Marquette University at Milwaukee in 1908, practicing for one year in Mount Horeb.

In 1910, he moved with his family to Spring Grove. He served in the medical corps during World War I and rose to the rank of major, remaining a member of the reserve medical corps.

Dr. Helland was a member of the American Legion; the Commercial Club; the National Association of Military Surgeons; the Olmsted-Houston-Fillmore-Dodge County Medical Society, the Minnesota State Medical Association, the American Medical Association; the Shrine and the Spring Grove A.F. and A.M. Lodge. He served as president of the Spring Grove Hospital for fifteen years and also served on the school board for a number of years. In 1950, the community of Spring Grove paid tribute to his many years of service.

He is survived by his wife, Julia; four daughters, Mrs. V. V. Lindgren, Portland, Oregon; Mrs. Ronald Shaw, Oakland, California; Mrs. Bevis Ash, Redding, California; Mrs. Dan Morris, Alamo, California; one son, Kenneth W. C. of Janesville, Wisconsin; four brothers, Dr. J. W. Helland and C. J. Helland of Spring Grove; Dr. C. A. Helland, Argyle, Wisconsin; and Randolph O. Helland, Portland, Oregon.

BERT R. KARN

Dr. B. R. Karn, who practiced at Ortonville for forty-seven years, died of a heart attack at the Dyckman Hotel in Minneapolis, January 4, 1955. He was sixty-five.

Dr. Karn, who operated a clinic in Ortonville with his son, J. Francis, began practice with his father in Ortonville in 1907. He received his medical degree the same year from the University of Minnesota.

Dr. Karn was born in Ontario, Canada, in September, 1882, and had his preliminary education in Ortonville. After graduation in 1907 from the University of Minnesota, he took his internship at Washington Hospital in Chicago, where he also took postgraduate work, specializing in eye, ear, nose and throat work in 1916.

Dr. Karn is survived by his wife, and three sons: J. Francis, Ortonville; Richard and William.

DENNIS MICHAEL O'DONNELL

Dr. D. M. O'Donnell died at his home in Ortonville, on December 5, 1954, after a long illness. Dr. O'Donnell had practiced at Ortonville for thirty-seven years. He was sixty-nine years old.

Dr. O'Donnell was born on September 28, 1885, at Aberdeen, South Dakota. In 1910, he graduated from the University of Illinois and was licensed to practice medicine in Minnesota, South Dakota, Illinois and California. He attended Aberdeen High School and Aberdeen State Teachers College at Aberdeen, graduating in 1906. He interned at Chicago Hospital for eighteen months. He practiced in Odessa, Minnesota, for one year; in Huron, South Dakota, for one year before coming to Minnesota to practice in Ortonville. He was a staff member of the Ortonville Evangelical Hospital.

Dr. O'Donnell served as physician for the Milwaukee Railway, the Fire Department and also was chairman of the Board of Health. In 1953, the community paid its tribute to him with a gathering in his home sponsored by the Civic and Commerce Association.

Reports and Announcements

MEDICAL MEETINGS

State

MINNESOTA STATE MEDICAL ASSOCIATION, annual meeting, Minneapolis, May 23-25, 1955.

National

American Cancer Society, Board of Directors and special committee meetings, Hotel Radisson, Minneapolis, June 2, 1955.

American College of Chest Physicians (Council on Postgraduate Medical Education) and Laennec Society of Philadelphia, eighth annual postgraduate course on Diseases of the Chest, Bellevue-Stratford Hotel, Philadelphia, Pennsylvania, March 7-11, 1955.

American College of Surgeons, sectional meeting, The Fort Harry, Winnipeg, Manitoba, Canada, April 25-26, 1955.

American Goiter Association, annual meeting Skirvin Hotel, Oklahoma City, Oklahoma, April 28-30, 1955.

American Medical Association, annual meeting, Atlantic City, New Jersey, June 6-10, 1955.

International

International Academy of Proctology, seventh annual meeting, Hotel Plaza, New York, New York, March 23-26, 1955.

International College of Surgeons, United States Section, Southwestern Division regional meeting, Shamrock Hotel, Houston, February 28-March 1, 1955.

Inter-American Congress of Radiology, Shoreham Hotel, Washington, D. C., April 24-29, 1955.

International Hospital Congress, Lucerne, Switzerland, May 30-June 3, 1955.

International Symposium on Cardiovascular Surgery, Henry Ford Hospital, Detroit, March 17-19, 1955.

AMERICAN BOARD OF OBSTETRICS AND GYNECOLOGY

The next scheduled Examinations (Part II) oral and clinical for all candidates for certification by the American Board of Obstetrics and Gynecology will be conducted at the Edgewater Beach Hotel, Chicago, Illinois, by the entire Board from May 12 through May 20, 1955. Formal notice of the exact time of each candidate's examination will be sent him in advance of the examination dates.

FAMILY DOCTORS' DAYS
at the
University of Minnesota Hospitals

All physicians are cordially invited to attend the following Family Doctors' Days which will be presented under the direction of the department indicated.

February 16—Division of Anesthesiology
March 16—Division of Urology
April 20—Division of Neurosurgery

Activities begin with luncheon at 12:15 noon with the staff of the Department in the Hospital Dining Room and will continue throughout the afternoon.

For further information, write the head of the department concerned or the Director, Department of Continuation Medical Education, University of Minnesota Hospitals.

NATIONAL HOSPITAL WEEK

Each year the nation sets aside one week in which to become better acquainted with its hospitals. National Hospital Week in 1955 will be May 8-14. During this week the attention of the American public is focused on our hospitals, in which one out of every eight of us receives care each year. The theme of National Hospital Week in 1955 will be "Your Hospital . . . A Tradition of Service."

National Hospital Week is sponsored annually by the American Hospital Association. Celebration of a National Hospital Day began in 1921 and was expanded to a week in 1953. National Hospital Week is traditionally built around the May 12 birthday of Florence Nightingale, the famous nurse crusader of the Crimean War, whose pioneer service led to the improvement of hospital care in both England and America.

AMERICAN HEARING SOCIETY

The American Hearing Society announces March 1 as opening date for competition for the 1955 Kenfield Memorial Scholarship, an award made annually to a prospective teacher of lipreading. Application blanks may be obtained by writing to the society's national headquarters, 817 14th Street, Northwest, Washington 5, D. C.

Deadline for returning completed applications is May 1. They are to be mailed to Mrs. Dorothy J. Cornett, 4310 S.W. 14th St., Coral Gables 34, Fla. Mrs. Cornett is chairman of the American Hearing Society's Teachers Committee.

Winner of the Kenfield Memorial award is entitled to take a teacher training course in lipreading from any school or university in the United States acceptable to the Teachers Committee. The scholarship is to be used within one year from the date of award.

A satisfactory applicant for the award must be a well-adjusted person with a pleasing personality, legible lips, good speech and voice and no unpleasant mannerisms. Graduation from college with a major in education, psychology and/or speech is a requirement.

Specifications for a hard-of-hearing contestant include 30 clock hours of private instruction in lipreading from an approved teacher or 60 hours of lipreading in public school classes under an approved teacher. Rules for competition state that an applicant shall plan to teach lipreading with or without other types of speech or hearing therapy.

PHYSICIAN PILOTS ORGANIZE

Some time ago several physicians simultaneously conceived the idea of forming a national society of flying physicians. Initial action was started by Mark E. DeGroff of Tulsa, Olkahoma, medical equipment manufacturer, who offered to act as a central office until preliminary arrangements could be made. A notice in the AOPA *Newsletter* brought forth over one hundred interested inquiries. About twenty-eight physician pilots attended the American College of Surgeons meeting in Atlantic City and twenty-four attended the AMA session in Miami. It was felt that enough interest was shown to warrant an attempt to organize.

It was decided that the purposes of this society should be scientific, educational, and social. Physicians have a considerable influence which should be passed on to everyone to promote greater aviation safety. Further, physicians who have this interest could learn much about the technical aspects of flying from association with each other.

The immediate objectives are: compilation of a complete list of physician pilots; appointment of temporary local area chairmen; the collection of ideas and suggestions; and encouraging physicians to fly to the AMA Meeting at Atlantic City, June 6-10, 1955.

A scientific and social program can be arranged at Atlantic City, if enough interest is shown.

Physician pilots who are interested are requested to send their names, plane flown and landing field to the local chairman of their area, or, if not known, to H. D. Vickers, M.D., 25 Jackson Street, Little Falls, New York, temporary chairman.

MENTAL HEALTH GRANT

The Hamm Foundation of St. Paul has announced a new grant to St. John's Institute for Mental Health at Collegeville, Minnesota.

Except for a nominal tuition fee to be paid by participants, the Foundation gift will cover the complete cost of three week-long pastoral psychology workshops to be held next August at St. John's University for clergymen of all faiths who are interested in mental health problems.

The first series of workshops were held last August. Originally planned for clergymen of the Upper Midwest, the workshops also attracted participants from California, Nebraska, Kentucky, Missouri, Illinois, Rhode Island, Washington, D. C., and Canada.

Minnesota physicians who served on the faculty were Doctors C. Knight Aldrich, Louis L. Flynn, Adelaide Johnson, Hyman S. Lippman, Howard P. Rome, and Clarence J. Rowe.

The second series of pastoral psychology workshops will be held next August. The following Minnesotans have been named as full-time faculty for next summer: Doctors David A. Boyd, Howard P. Rome, Don Hastings, and Louis L. Flynn. Other physicians, such as Dr. Adelaide Johnson and Dr. Hyman S. Lippman, will serve as special lecturers.

NORTHFIELD CITY HOSPITAL

On January 5, 1955, the Northfield City Hospital Staff elected the following officers for the year 1955: Chief of Staff, George N. Rysgaard, M.D.; Vice President, Robert F. Mears, M.D.; Secretary-Treasurer, Donald Peterson, M.D.

The Staff meets once a month for business and a scientific program, and once a month for a pathological conference conducted by Dr. John I. Coe, pathologist.

CONTINUATION COURSES

A continuation course in *Emergency Surgery for General Physicians* will be presented by the University of Minnesota, March 31 to April 2, at the Center for Continuation Study. The management of injuries and other acute surgical problems will be taken up in detail. The program will be presented under the direction of Dr. Owen H. Wangensteen, professor and chairman, Department of Surgery.

* * *

The University of Minnesota and the Minnesota Heart Association will join in sponsoring a continuation course in *Cardiovascular Diseases for General Physicians* which will be held at the Center for Continuation Study from March 21 to 23. The common cardiovascular disorders will be discussed and treatment will be emphasized. The course will be presented under the direction of Dr. C. J. Watson, professor and head, Department of Medicine.

* * *

A continuation course in *Gynecology for General Physicians* will be presented by the University of Minnesota at the Center for Continuation Study from April 14 to 16, 1955. This year's course, which will be presented under the direction of Dr. John L. McKelvey, Professor and Head, Department of Obstetrics and Gynecology, will deal with the general problem of vaginal bleeding. The various causes of vaginal bleeding will be discussed from the standpoint of diagnosis and management.

* * *

The University of Minnesota will present a continuation course in *Radiology for General Physicians* from April 11 to 13, 1955, under the direction of Dr. Leo G. Rigler, Professor and Head, Department of Radiology.

Registrants for the course will spend most of their time in the University Hospital Department of Radiology reading films and carrying out procedures in association with members of the faculty of that department. A minimum of didactic material will be presented. Because of the nature of this course, registration will be strictly limited. Early application is therefore suggested. Accommodations will be available in the Center for Continuation Study as usual.

* * *

The University of Minnesota announces a continuation course in *Allergy and Chest Diseases for General Physicians* to be held at the Center for Continuation Study from April 18 to 20, 1955. Special emphasis will be placed on the management of commonly-met problems in these fields. Skin testing methods will be demonstrated and discussed. The program will be presented under the direction of Dr. C. J. Watson, Professor and Head, Department of Medicine.

LICENSURE EXAMINATION

An examination for medical licensure will be held by the Minnesota State Board of Medical Examiners beginning on Tuesday, June 14, 1955, continuing on Wednesday and concluding with a practical examination on Thursday, June 16, 1955. Applications for such examination, accompanied by required credentials and fees, should be on file thirty days prior to the examination at the headquarters office, 230 Lowry Medical Arts Bldg., Saint Paul 2, Minnesota.

RAMSEY AUXILIARY REPORTS ACTIVITIES

Mrs. L. T. Simons

The Woman's Auxiliary to the Ramsey County Medical Society resumed its activities after a short holiday rescess. On January 17, a Board meeting was held in the Medical Library, with Mrs. W. P. Gardner, Saint Paul, president, presiding. Members made cancer dressings during and following the meeting.

On January 24, a luncheon meeting was held at the Athletic Club. The program consisted of a showing of a rehabilitation film. Winners of the TB Essay Contest read their prize-winning essays at the luncheon.

A delegation of Ramsey County auxiliary members attended the annual Mid-Winter Board meeting of the Woman's Auxiliary to the Minnesota State Medical Association, held on February 10 at the Town and Country Club. Officers and state committee chairmen presented reports, and members enjoyed a pleasant luncheon.

In Memoriam

DENNIS MICHAEL O'DONNELL

(Continued from Page 133)

He was a member of the West Central Minnesota Medical Society, the Minnesota State Medical Association, and the American Medical Association.

Dr. O'Donnell is survived by his wife, Florence, and one daughter, Kathleen.

LEON GRANT SMITH

Dr. Leon G. Smith, prominent Montevideo physician and long-time councilor active in the Minnesota State Medical Association, died of a heart ailment at his home in Montevideo, January 13, 1955. He was sixty-seven years old.

Dr. Smith was elected Third District councilor to the Minnesota State Medical Association in 1947, serving through 1954, when he retired because of ill health. He has been active and well known in the western part of the state for many years for his activities in medical organization work. He served as president of the Camp Release District Medical Society in 1925 and 1926, having served on various committees also. For many years he was a member of Chippewa County's Advisory Committee to the Division of Social Welfare, and was also a member of various other state and county committees.

Dr. Smith was born on September 27, 1887, at Benson, where he obtained his preliminary and high school education. He received a B. S. degree from the University of Minnesota in 1909 and graduated in medicine in 1910. He then served a one-year internship at Minneapolis City (now General) Hospital.

He served in the Army Medical Corps during World War I and took several postgraduate short courses at Dyon, France, during this time. Dr. Smith has practiced at Montevideo since 1912, except for his war service and two years of practice at Buffalo, Minnesota.

He was a member of the Camp Release District Medical Society, the Minnesota State Medical Association, and the American Medical Association.

Dr. Smith was a staff member of the Montevideo Hospital and served for many years on the local Board of Education.

He is survived by his wife, Edith; four children, William G., Greenwich, Conn.; Mrs. Paul Larson (Margaret), Sacramento, Calif.; Eugene A. and Leon Gordon, both of Montevideo; one sister, Mrs. Grace Osborne, Minneapolis, and fifteen grandchildren. His parents and one sister preceded him in death.

Of General Interest

Dr. and Mrs. Titus C. Kreuzer of Marshall, Minnesota, are on an extended European vacation. They will fly to Lisbon, Portugal, then tour Spain, before settling down for a month at Palma de Mallorca.

Before returning home in April, the Kreuzers also plan to visit France.

* * *

Dr. H. L. Williams, of the Eye, Nose and Throat Department, Mayo Clinic, Rochester, is scheduled to present a paper on "Ménière's Disease" at the annual convention of the American Medical Association in Atlantic City, New Jersey, which will convene June 6-10, 1955.

* * *

Dr. Merrill D. Chesler, Minneapolis, spoke on "Traumatic Deformities and Their Reconstruction" at a luncheon meeting of the Junior Section of the Hennepin County Bar Association in Minneapolis, January 28, 1955. The talk was illustrated with slides in color.

* * *

Dr. Della Drips, Oronoco, is the Medical Woman of the Year for Branch Twenty-six, of the American Medical Women's Association, for Minnesota. "Her pioneer investigations in the field of hormones; her study of gynecologic endocrinology in Berlin; the development of the first laboratory in this field at the Mayo Clinic; her authoritative knowledge of the subject; and her readiness and ability to teach, has resulted in many warm friends among those who have been privileged to know and work with her."

Dr. Drips retired from the active practice of medicine and her specialty of gynecology at the Mayo Clinic in 1949.

* * *

The January issue of *The Journal of the American Medical Women's Association* is the special number of Branch Twenty-six, Minnesota, with **Dr. Nellie N. Barsness,** Saint Paul, as guest editor.

Articles included were "Anoxia and the Surgical Patient," **Dr. Margaret C. Anderson,** Mankato; "Primary Amenorrhea," **Dr. Della G. Drips,** Oronoco; "Cerebral Vascular Accidents," **Dr. Marguerite Schwyzer,** Saint Paul; and a special article, "Alaskan Interlude," by **Dr. Catherine Burns,** Albert Lea.

* * *

Dr. David M. Potek has opened offices for general practice at 3657 Emerson Avenue North in Minneapolis following completion of a fellowship at Glen Lake Sanatorium, which he began in January, 1952. Dr. Potek was engaged in practice in International Falls from 1936 to 1940. He served in the Army from 1940 to October, 1945, when he returned to International Falls for a six-year period.

Four physicians and surgeons who recently completed fellowships in the Mayo Foundation have been appointed to the staff of the Mayo Clinic. They are **Drs. Richard Reitemeier, Norman G. Hepper** and **Paul A. Green,** all in general medicine, and **Dr. C. Roger Sullivan,** who will be in orthopedic surgery.

* * *

Dr. Gordon R. Kamman of Saint Paul spoke at the January 11 meeting of the Cerro-Gordo County Medical Society in Mason City, Iowa. Dr. Kamman's topic was "Psychometrics in General Practice." About fifty society members were present.

* * *

Dr. and Mrs. Gilbert Wheeler were honored by the Roseau Lions Club recently. The Wheelers, who have resided in Roseau for several years, are moving to Winnipeg, where Dr. Wheeler will take a four-year course in radiology.

* * *

Recently appointed county jail and work farm physician is **Dr. John V. Thomas** of Duluth. He succeeds **Dr. Cyril Smith,** coroner-elect and former jail physician, and **Dr. J. W. Ekblad,** Duluth, retiring coroner and workhouse physician.

* * *

Dr. Leo A. Nash of St. Paul attended the fortieth annual meeting of the Radiological Society of North America in Los Angeles, California.

* * *

A Clinton man, **Lt. Paul A. Williams,** was one of eighty-three Air Force physicians to receive diplomas recently from the School of Aviation Medicine at Randolph Air Force Base, Texas. He is presently assigned to the USAF infirmary at the Harlingen Air Force Base, Texas.

* * *

President of the staff at Murray County Memorial Hospital for 1955 is **Dr. Hugh D. Patterson,** Slayton. Vice President is **Dr. Thomas Harada** of Lake Wilson, and secretary is **Dr. D. D. Nywall** of Slayton.

* * *

Dr. S. F. Haines has been re-elected chairman of the Mayo Clinic board of governors. **Dr. J. T. Priestley** will be vice chairman; **J. W. Harwick,** secretary; and **Dr. H. R. Butt,** second vice chairman.

* * *

New president of the Blue Earth County Medical Society is **Dr. J. J. Eustermann** of Mankato. He succeeds **Dr. R. W. Kearney.** Other new officers include **Dr. William S. Chalgren,** vice president, and **Dr. George R. McNear, Jr.,** secretary-treasurer. The election was held at the December annual meeting. Delegates to the Minnesota State Medical Association will be **Dr. Orville Jones** and Dr. Chalgren.

Dr. Philip R. Heise of Winona was elected president of the Winona County Medical Society at the group's quarterly meeting last month. Other officers named for one-year terms are: **Dr. W. O. Finkelnburg,** Winona, vice president; **Dr. L. J. Wilson,** Winona, secretary, and **Dr. Pat Rollins,** St. Charles, treasurer.

* * *

Dr. Chester E. Thiem, Mankato, has been elected to serve another term as president of the Immanuel Hospital medical staff. Others elected to positions on the Mankato hospital staff are **Dr. H. O. Morgan,** Amboy, and **Dr. B. Niles Batdorf** of Good Thunder. Re-elected to the executive committee were **Dr. James Anderson** and **Dr. Robert Engstrom,** both of Mankato, with **Dr. Mervin W. Dobson,** Mankato, as new committee member.

* * *

At a regular monthly meeting of the staff of St. Michael's Hospital, Sauk Centre, **Dr. A. B. Nietfeld** was elected president of the staff. **Dr. J. F. DuBois, Jr.,** will be vice president, and **Dr. F. H. Baumgartner,** Albany, will be secretary.

* * *

New president of the Red River Valley Medical Society, succeeding **Dr. Alan McKaig** of Red Lake Falls, is **Dr. Harold Thysell,** Crookston. **Dr. Byron R. Kinkade** of Ada was elected vice president and **Dr. R. O. Sather** was named secretary-treasurer. Guest speaker at the meeting was **Dr. James Garvey** of Minneapolis, who talked on emotional disturbances of children.

* * *

Dr. Roger W. Ridley, a member of the Mayo Clinic staff since 1948, has resigned to enter private practice in Riverside, Calif. Dr. Ridley has been a consultant in the section of anesthesiology and intravenous therapy at the Clinic and an instructor in anesthesiology in the Mayo Foundation since 1948.

* * *

Dr. Stanley S. Chunn of Willmar, formerly associated with the Lakeland Medical Center in Willmar, is now engaged in private practice. Dr. Chunn specializes in eye, ear, nose and throat.

* * *

Dr. K. A. March of Cambridge, former chief of staff at the Community Hospital, has moved to San Diego, where he will take up his practice.

* * *

Dr. Samuel Miller, former radiologist at the Naeve Hospital in Albert Lea and in hospitals at Wells and Blue Earth, has joined the DePuy-Sorkness medical clinic in Jamestown, North Dakota. Dr. Miller, who once practiced general medicine in Jamestown, will specialize in radiology.

* * *

Dr. Maxwell Barr was elected chief of Maternity Hospital, Minneapolis, at the hospital's annual medical staff dinner meeting on January 18. He succeeds Dr. Milton Abramson in the office. Other officers include **Dr. Marie Moorhead,** vice president; **Dr. Francis Swain,** secretary, and **Dr. Sidney Scherling,** treasurer. Chief speaker at the meeting was Dr. John Randall, professor and chief of obstetrics and gynecology at the University of Iowa.

* * *

After completing a three-year residency in obstetrics and gynecology at the Mayo Clinic, Rochester, **Dr. Walter Eisenman** has moved to Hibbing, where he is associated with the Mesabi Clinic. He was formerly with the clinic for four years, practicing in Coleraine.

* * *

Copies of a book written by the late **Dr. J. A. Sanford** are now available at the Sanford Hospital, Farmington. The book, entitled, "A General Practitioner Speaks," was written by Dr. Sanford over a number of years and deals with the subject of general practice. Dr. Sanford died on November 15, 1954, while doing the final proofreading for the volume.

* * *

At a meeting of the Mahnomen County board of commissioners in January, **Dr. Kenneth W. Covey,** Mahnomen, was named as a member of the county board of health.

* * *

Dr. W. H. Valentine, Tracy, president of the county tuberculosis and health association, announced that a tuberculin testing survey was carried out at schools in Marshall from January 24 through February 4.

* * *

The board of commissioners of Mille Lacs County has elected **Dr. W. R. Blomberg,** Princeton, a member of the county board of health.

* * *

Dr. Bernard J. Spencer, Minneapolis, has been elected a diplomate of the American Board of Surgery. A graduate of the University of Minnesota Medical School, Dr. Spencer spent two years as assistant surgical resident at Boston Children's Hospital, Boston, and three years as a surgical fellow at the Mayo Clinic, Rochester. He is now practicing pediatric surgery in Minneapolis.

* * *

The commissioners of Stearns County have appointed **Dr. John B. Beuning,** St. Cloud, a member of the county board of health. **Dr. Charles F. Brigham, Jr.,** St. Cloud, has been appointed Stearns County physician.

* * *

Dr. S. W. Giere, Benson, showed motion pictures he had taken in the Scandinavian countries at a public gathering in the Benson high school on January 22.

* * *

Dr. M. Duane Sommerness, clinical director at Fergus Falls State Hospital, was named temporary acting superintendent of Hastings State Hospital in January. He was to serve while Dr. Jorge Lazarte, clinical director at Rochester State Hospital and acting superintendent at Hastings, was on a vacation trip to South America. Dr. Dale Cameron, medical director of the Department of Public Welfare, said that Dr. Lazarte would return to his part-time post at Hastings after his vacation unless a full-time superintendent had been found in the meantime.

* * *

The new West St. Paul Medical Center was opened for the practice of medicine on January 3. The center is staffed by **Dr. J. A. Malerich, Sr., Dr. J. A. Malerich, Jr., Dr. Joseph P. Connolly,** and a dentist, Dr. H. E. Schad.

* * *

Dr. Robert P. Koenig, Paynesville, has reported for active duty in the Air Force. Dr. Koenig, who has been associated with the Myre Clinic at Paynesville for the past two years, expects to be stationed at the Air Force Hospital at Geneva, New York.

* * *

Dr. Paul A. Robertson, Austin, gave a talk on health at a meeting of the Woodson 4-H Club early in January.

* * *

Dr. George Haggard, Minneapolis, celebrated his ninety-eighth birthday on January 18.

* * *

Dr. Charles Mayo, Rochester, is one of forty-one distinguished Americans named to a lifetime appointment on the college of electors of the Hall of Fame for Great Americans. The members elect candidates to the Hall of Fame, which is located on the Bronx campus of New York University.

* * *

Dr. H. P. Van Cleve, Austin, attended a one-week postgraduate course in dermatology at New York University in mid-January, following which he vacationed in Florida for several weeks.

* * *

Dr. Milton M. Howell, Glencoe, has purchased a half-interest in the Glencoe Clinic. Dr. Howell has been associated in the clinic with **Dr. C. W. Truesdale** for the past year.

* * *

Dr. D. H. Bessesen, Olivia, has been elected chief of staff of the Renville County Hospital. **Dr. J. A. Cosgriff, Sr.,** Olivia, was elected vice chief of staff, and **Dr. Donald Metz,** Buffalo Lake, was named secretary-treasurer.

NEW LOCATIONS

Dr. Robert J. Cesnik, who has been associated with Dr. L. M. Evans for the past five years, has entered the Army. He will be stationed at Fort Sam Houston, Texas.

* * *

Dr. James Nixon, who has been in the Navy about two years, has returned to his practice at the Cuyuna Range Clinic at Crosby. **Dr. R. A. Kallsen,** who has been associated with **Dr. C. M. Marshall** and **Dr. R. E. Kelley,** at the Clinic, has left for California to join his family.

* * *

Dr. Donald R. McFarlane, who completed his internship at General Hospital in Minneapolis in July, has become an associate in the Oliver Clinic at Graceville. **Dr. C. J. Swendseen,** who formerly practiced at Alexandria, also is a new member of the Clinic.

* * *

Dr. H. C. Habein, Jr., of Rochester, who was called into active service with the Air Force in November, is now with the Air Force Hospital in Wiesbaden, Germany. Capt. Habein is the son of **Dr. Harold C. Habein** of Rochester.

* * *

Dr. William Furlow, formerly of Belle Plaine, has taken over the practice of the late Dr. R. W. Maertz in Faribault. Dr. Furlow is a native of Rochester.

* * *

Dr. Stanley E. Roberts, a former Fellow in surgery at Mayo Clinic, is now associated in practice with **Dr. Paul F. Meyer** and **Dr. Robert P. Meyer** at Faribault.

* * *

Dr. Bela Gallo is now located at Taconite Harbor after fifteen months at Lake Bronson. Dr. Gallo has accepted a position with the Erie Mining Company.

* * *

Dr. William Hunt, obstetrician and gynecologist of the Mayo Clinic staff, has moved to Fergus Falls, where he is now associated with the Park Region Medical Center.

* * *

Dr. John C. Mickelson has been granted a two-year leave of absence from the Mankato Clinic at Mankato. He began a residency in urology in Durham, North Carolina, January 1.

* * *

Dr. James W. Halvorson, formerly of Goodhue, has purchased the practice of Dr. Martin G. Flom at Zumbrota. Dr. Flom has accepted a position on the staff of the Veterans Hospital, Fargo. Dr. Halvorson recently completed a tour of duty in the Navy.

* * *

Dr. Kermit L. Stensgaard, formerly of Lafayette, California, is now associated with a clinic at Thief River Falls.

* * *

It was announced in mid-January that **Dr. James S. Barr,** formerly of Wells, planned to open a practice at Elmore.

MINNESOTA BLUE SHIELD-BLUE CROSS

Blue Shield News

At its meeting in Miami, Florida, on November 30, 1954, the Board of Trustees of the American Medical Association approved the appointment of a commission to conduct a comprehensive survey of the different types of plans which provide people financial assistance in obtaining medical services. Interest in the matter was stimulated through the Second Conference on Management-and Union-Sponsored Health Centers, arranged by the American Medical Association, and held February 24, 1954, in Louisville, Kentucky.

On August 27, 1954, the Board of Trustees of the American Medical Association appointed a Task Force to consider the desirability of appointing a commission to survey the various types of medical care plans in effect. This Task Force in November, recommended to the Board of Trustees that it appoint such a commission for this purpose.

Among the types of plans which are likely to be studied by the commission are prepaid closed-panel plans, non-contributory closed-panel plans, non-contributory free-choice plans and industrial medical programs. Such plans include the Health Insurance Plan of Greater New York and the Kaiser-Permanente plans of California, as well as many others. In addition to these, indemnity insurance plans, prepaid full payment plans and combination indemnity service plans will undoubtedly be studied by the commission. Such plans include the various Blue Shield plans throughout the country.

It has been reported that the commission will have as its chairman, Dr. Leonard W. Larson of Bismarck, North Dakota, a trustee of the American Medical Association. Minnesota physicians will be interested in knowing that Dr. F. J. Elias, of Duluth, has been appointed a member of the commission. The only member of the commission who is not a physician is Jay Ketchum, executive vice president of Michigan Medical Service. Dr. Leo Price, director of the Union Health Center of New York, is the only physician member of the commission who is not an American Medical Association trustee, delegate or council member. Other members of the commission are Doctors David B. Allman, Homer L. Pearson, Jr., Joseph D. McCarthy, Percy Hopkins, H. Russell Brown, James R. Reuling, H. Gordon McLean, John Conway and William P. Sheppard.

Blue Cross News

Blue Cross, through twenty-five years, has given more people more benefits than all other types of hospitalization plans combined. The start of the Blue Cross plan was made possible at Baylor University Hospital for Dallas school teachers to protect themselves against the sudden cost of unexpected hospital bills. Each teacher paid a small amount monthly into a common fund and this fund paid the expenses of those who had to be hospitalized.

Out of this idea of people helping each other grew Blue Cross. It spread to communities across the nation. Minnesota Blue Cross, one of the pioneer prepaid hospitalization plans, was created in 1933 when there were few, if any, people in the state with any protection against hospital expenses. Since that time, just twenty-two years ago, Minnesota Blue Cross has enrolled over one million subscribers in Minnesota.

Today, throughout the nation, 47 million people are protected by Blue Cross. Blue Cross has grown because it has held fast to its ideal of public service. Its aim still is to help people secure the hospital care they need.

BOOK REVIEWS

Books listed here become the property of the Ramsey, Hennepin and St. Louis County Medical Libraries when reviewed. Members, however, are urged to write reviews of any or every recent book which may be of interest to physicians.

BOOKS RECEIVED FOR REVIEW

VIRAL AND RICKETTSIAL DISEASES OF THE SKIN, EYE AND MUCOUS MEMBRANES OF MAN. Harvey Blank, M.D., Squibb Institute for Medical Research, Columbia University, University of Pennsylvania; and Geoffrey Rake, M.B., B.S., University of Pennsylvania, Wistar Institute for Anatomy and Biology, and Squibb Institute for Medical Research. 285 pages. Illus. Price $8.50, cloth. Boston: Little, Brown & Co., 1955.

PLANNING FLORIDA'S HEALTH LEADERSHIP—FLORIDA'S HOSPITALS AND NURSES. John M. MacLachlan, Ph.D. 122 pages. Illus. Price $1.50, paper cover. Gainesville, Florida: University of Florida Press, 1954.

DRUGS IN CURRENT USE 1955. Edited by Walter Modell, M.D., Associate Professor of Clinical Pharmacology, Cornell University Medical College. 148 pages. Price $2.00, flexible binding. New York: Springer Publishing Co., 1955.

HEALTH SUPERVISION OF YOUNG CHILDREN. 180 pages. Price $2.00, paper cover. New York: American Public Health Association, 1955.

The volume, "Health Supervision of Young Children," has been five years in preparation and is the product of collaboration by more than sixty prominent professional persons. It bears the endorsement of the American Academy of Pediatrics, U. S. Children's Bureau, National League for Nursing, and Association of State Maternal and Child Health and Crippled Children's Directors.

Latest available information about well infants and pre-school children is organized so as to be helpful to persons professionally concerned with child health, whether in private practice or in the fields of public health, welfare or education.

Part I, planned for physicians, nurses and other professional persons, is a guide to health supervision, incorporating newest techniques in parent counseling and health appraisal and care. It deals primarily with everyday problems in normal development but also gives consideration to the handling of less usual problems and abnormal conditions.

Part II, written especially for professional persons concerned with community health and welfare, is a guide to carrying out child health supervision through the child health conference, the "well-baby clinic" or "child health station."

This is the first of a series of manuals being prepared by the A.P.H.A. Committee on Child Health, under the chairmanship of Dr. Samuel M. Wishik of the University of Pittsburgh Graduate School of Public Health. The text was written by Nina Ridenour, Ph.D., staff consultant to the committee.

Original Contributions

Medical Aspects of Peptic Ulcer

JAMES MYHRE, M.D.
Minneapolis, Minnesota

PEPTIC ULCER is a sharply circumscribed loss of tissue resulting from the digestive action of acid gastric juice. It is clearly differentiated from an erosion in that peptic ulcer is a penetrating process involving the muscularis mucosa as well as mucosa.

It has been estimated from autopsy statistics that ten per cent of all individuals at some time or another in their lives have suffered from a chronic gastric or duodenal ulcer. The duodenal ulcer occurs about four to one in the male whereas gastric ulcer occurs three or four to one in the female. A further breakdown as to sex includes approximately only a two percent incidence of perforation of peptic ulcers in the female.

Peptic ulcer may occur in the lower esophagus, stomach, upper portion of the duodenum, in the small bowel when it is anastomosed to an acid-bearing section of the gastrointestinal tract, and very rarely in a Meckel's diverticulum in the jejunum or ileum. In the latter instance it occurs with ectopic gastric mucosa. The vast majority are in the first one to one and one-half inches of the duodenum or the duodenal bulb.

Etiology is a big subject but certain elementary things seem very definite and also pertinent as far as understanding the problem of treatment is concerned. It appears to be simply a digestion of tissue by the acid gastric juices. The old dictum of "No acid, no ulcer" seems incontestable. Peptic ulcer occurs only in those portions of the gastrointestinal tract exposed to the action of the acid gastric juice, and peptic ulcer does not occur in the complete absence of acid gastric juice. The psyche has been increasingly incriminated. There is at present a strong association of peptic ulcer with tension, nervous instability, fatigue and worry. Frequently the emotional aspects in etiology are lacking in gastric ulcers. The psychoanalyst finds strong dependent wishes which may be overt or not at all obvious in these people. In the group with hidden dependency these wishes are rejected by the patient's conscious personality and frequently overcompensated for in a capable energetic attainment of social or economic success. It has been said that a person could have a rousing business if he himself had a good ulcer and had twelve ulcer patients working for him. Harry Truman may have been nearer the core of things than he realized when he spoke of a three-ulcer man in a four-ulcer job. It has been said that hyperthyroidism originated from stress in the home or family and an ulcer originates from stress with external environment, e.g., a business or job. Wolf and Wolf in their patient, Tom, with a gastric fistula, observed hypersecretion during tense anxiety and noted then the transition from a mucosal erosion into an ulcer by the digestive action of acid gastric juice. During the Blitz in London there was a very definite increase in perforation of ulcers. Patients with chronic recurring ulcer distress frequently correlate an exacerbation with fatigue, stress, or tension.

The patient generally gives a history which is rather definite. He might describe the pain as burning, hurting, gnawing, annoying, or aching or just a dull distress or an awareness of discomfort. Sometimes the word "hunger pain" is used but actually hunger pain is an intermittent type of distress whereas ulcer distress is steady and continuous from fifteen minutes up to one or more hours. The presence of a pain in the back suggests chronic perforation. Chronicity of pain is generally characteristic for most patients with an

---

Presented before the Minneapolis Academy of Medicine, April 19, 1954.

Dr. Myhre is clinical assistant professor of medicine in the University of Minnesota Medical School, Minneapolis, Minnesota.

ulcer for they experience their pain over a period of years. Histories of twenty to thirty years of distress are not uncommon but the common incidence is stated as being between five and eight years. Of course, one can find asymptomatic peptic ulcer or peptic ulcers of very brief duration as only a few days or few weeks. Generally one can bring out or the patient will spontaneously volunteer a daily rhythm to his distress. If the patient is given time and encouraged to give a "typical day," he will frequently describe the distress as coming on one to four hours after eating and he will get relief by eating, drinking milk, or taking soda. Vomiting and rest frequently help. Frequently he will describe waking with distress between midnight and two o'clock in the morning. This suggests pyloric obstruction and/or an acutely inflamed ulcer with a very high gastric secretion. The periodicity of ulcer distress is quite interesting and is classically stated as being in the spring and fall of the year. Many people do notice this periodicity but statistical studies do not bear this out except perhaps in farmers, for the greater distribution is more through the winter months. Periodicity may be correlated with infections, emotional stress, fatigue, or strain.

The final court of appeal is the x-ray or gastroscopic examination. Frequently there is a negative x-ray examination in a patient with a classical ulcer history. In this instance repeating the x-ray will frequently bring out the true state of affairs although there are errors depending on the efficiency of the x-ray examination, body type of the individual, and the difficulty in demonstrating posterior wall lesions. These people should be considered for gastroscopic examination.

When confronted with patients with gastrointestinal distress, part of the job is to decide which patients should have the benefit of x-ray examination. Obviously, the severity of the complaint is considered and whether or not it fits in with what is called classical ulcer distress. In the uncomplicated ulcer, it is quite unusual to have distress before breakfast, and noting this you may be much less inclined to feel an x-ray examination is necessary. The pain of an irritable bowel is much more likely to be intermittent and spread out over the abdomen, and classically the patient will obtain good relief with a good belch or particularly by flatus or a bowel movement. If the patient has hypertension, it is less likely that he has a peptic ulcer. Food relief is strongly suggestive, but soda relief is not entirely conclusive for it produces a belch which can cause relief of functional gaseous distress. Just nausea is uncommon with peptic ulceration, although it is very occasionally the only symptom in a gastric ulcer. A minor pearl is that epigastric distress which disappears with a dark stool is likely due to peptic ulcer. Peptic ulcer is rare in hypoparathyroidism and not uncommon with hyperparathyroidism. It is apparently rare with adrenocortical hyperactivity of the adrenogenital type. Ulcers frequently heal in the first part of pregnancy, and the general incidence in females goes up after menopause. On physical examination, the main finding is rather localized epigastric tenderness over the lesion. On laboratory examination, the gastric analysis is most helpful. "No acid, no ulcer" is most helpful in cataloguing the patient's distress. It is not infrequent, unfortunately, that a gastric analysis shows no free hydrochloric acid and on being repeated two or sometimes three times occasionally will show a plentiful supply of acid. Apparently the tip of the aspirating tube is in the esophagus or is passed into the duodenum. Blood in the stool by Guaiac test is, of course, suggestive of an ulcer with bleeding.

Relief of distress is generally easy. The patient hardly needs a doctor for this but just some advice from an ulcer friend or Aunt Nellie who has taken soda bicarbonate most of her life. Curing an actual ulcer crater is a bigger job, but the real challenge and the real job of the physician is healing the patient's tendency to recurrent ulcer formation or in other words healing a chronic disease. This generally involves changing his reactions to his environment.

Rest is perhaps the most important thing. This is best obtained in a hospital for from two to three weeks, and this is particularly true when the peptic ulcer is first discovered for it is here that the patient will get the best orientation which is so desirable at the onset in his probable chronic disease. It is in this new ulcer group that the best chance for a permanent healing of the disease is found. I have a friend who has a large number of patients apparently of a two to three packages of cigarettes, eight to ten highballs, and sixteen to eighteen hours a day type. They characteristically always have another $25,000 to $50,000 deal coming up the next day, and therefore continually put off concentrated treatment until the physician, who has considerable stature, has been known to go into their offices and take them by the arm to the hospital. There he pulls the shade, closes the door, orders that there be no telephone calls, no telegrams, no mail, and no visitors (probably particularly the patient's wife). Then with a minimal amount of medication and diet in a matter of a few days, the patient quickly becomes comfortable. Alleviating the chronic tension and fatigue of these people is of the utmost importance and is very nicely abetted by the cheap and practical phenobarbital in sufficient doses so that they can easily succumb to your good advice to never resist an urge to doze. Time should be taken to explain an ulcer to the patient, and this is most easily done with the patient in the hospital. You then can also further observe his reaction to himself, his business, his family, and his environment. I find it most helpful to sit down with a piece of paper and draw out the rough diagram of the stomach, duodenum, small bowel, and colon. Many patients have no appreciation of what the word ulcer means, and some understanding comes for the first time when you compare it to the collar sore on a horse, varicose ulcer on a lady's leg, or a running sore on a dog. Then you can very profitably carry it further by telling them that the acid in their stomach is just like acid in a cream station or acid from their car battery. A previously rather uninterested person becomes rather interested with this explanation and responds rather dramatically to the question, "What do you suppose would happen if battery acid or cream station acid were dropped in the collar sore of a horse for twenty-four hours a day?" He will then understand the value of rest when he realizes that tension and anxiety greatly increase the formation of acid. He will then understand that the frequent feedings are intended to neutralize the acid. He should, of course, entirely and forever quit smoking and drinking. This is not easy to do, of course, but it is best done in the hospital with the help of some sedation. I oversimplify it, but get the point across by telling them about the gastric analysis. I explain that if their gastric analysis showed thirty degrees and the tube were left in place and he were to smoke a cigarette, then the acid if it were aspirated again might show sixty degrees of acid. This makes sense to the patient and makes it much easier for him to quit smoking. Of course, the only way is to quit completely and not to "taper off." Spending this amount of time with the patient convinces him that you are interested, and your interest and enthusiasm are an exceedingly potent weapon in the therapeutic program.

The classical Sippy type of diet has its dating back to antiquity but was organized by Sippy and has very well stood the test of time. Ulcer treatments and ulcer drugs come and go many times a year, and the three to four ounces or half glass of milk and cream stands the test of time. This should be given with regularity on the hour from seven in the morning until seven at night. The half glass is important as it allows physiologic stomach rest, and this, too, should be explained to the patient inasmuch as large feedings cause distention and increased secretions. It is unnecessary in most instances to add antacid. It is expensive and just the milk alone is sufficient with the Sippy diet program of gradually increasing foods like poached or boiled egg, cooked cereal, toast, pureed fruits and vegetables, rice, jello, custard, chicken, and ground beef. In order to impress the patient of the necessity for this diet, you must know about it yourself and be convinced about it. The "three bland feedings a day" has no place in the treatment of peptic ulcer. The drug companies have flooded the market with multiple antacids and minor insignificant variations of them all. When you explain to the patient, as you should, that his ulcer treatment may take anywhere from six months to two years and then figure out what his cost would be for antacids, you will realize that it is not economically desirable. If you elect to add one of the aluminum hydroxide preparations as an antacid, it is probably best done on the half hour from 7:30 in the morning until 7.30 at night. A multiple vitamin preparation should be included on a Sippy diet.

The antisecretory drugs are the great hope in present peptic ulcer investigation and the emphasis in research has swung away from antacids to this type of medication. Banthine is the original and best known of all the drugs, and at the present is preferred because it is so well developed. It is hoped that some of the many brother and sister preparations will have less of the side effects of dryness of the mouth, blurring of vision, and slowing of micturition and above all not to be so variable and unpredictable in their effect. Our standard procedure is to give one hundred milligrams of Banthine at eight p.m., two a.m., eight a.m., and two p.m. or every six hours around the clock. We have the patient set his alarm clock at two a.m. to do this. At the present time, the antisecretory drugs must just be considered an adjunct to the rest and dietary program. It is rather disconcerting to see some of the sales propaganda encouraging the use of antisecretory drugs alone with three bland meals.

During the daily hospital visits, the various features of ulcer management are discussed with the patient, and he is encouraged to ask questions. The complications of hemorrhage in the form of tarry stools or coffee-ground vomitus should be mentioned. The symptoms of perforation should be impressed on the patient, and the necessity of getting to a physician early should be stressed. Pyloric obstruction should be mentioned. After the orientation in the hospital, the patient should have well in his mind that relief of his distress is easy and, of course, no indication whatever of degree of healing. He should also understand that complete healing is a slow process, and in our patients we do not even bother in the case of a duodenal ulcer to repeat the x-ray for evidence of healing any sooner than three months. The duodenal ulcers heal slowly, and the patients also are a little inclined to relax if there is no x-ray evidence of a crater. It is impossible to know when the ulcer crater has been completely filled in, and the patient should understand that his efforts and your efforts should be toward the healing of the disease, and this is a six-months-to-a-year program. You should discuss with him things that aggravate him and discuss with him getting full nights of rest, straightening things out on his job, getting a nap over the weekend, getting outdoors every day, and getting a regular vacation. For many years or perhaps his whole life, he should plan on a glass of milk in midmorning and midafternoon. We keep these patients in the hospital routinely for two weeks and then keep them out of work if possible one or two weeks more after which time they have then progressed from the hourly milk feedings of the first twenty-eight days of the Sippy diet and are then ready for the convalescent ulcer diet which requires a half glass of milk or milk and cream twice in the morning and twice in the afternoon at approximately an hour's interval. After hospital discharge we see the patient at two-to-four-week intervals in the office and carefully review his diet, his rest program, and his medications. Frequently the Banthine is continued up to two to six months, and sometimes we substitute tincture of belladonna in the latter part of this period. Tincture of belladonna should be begun at approximately fifteen drops three times a day before meals and at bedtime and increased two drops per day until the patient notices some visual symptoms. This might be anywhere from twenty-five to thirty to forty drops four times daily. When the patient notices symptoms referable to his eyes, then he should decrease the dose two drops and maintain it at this level. You should reassure the patient that if he has a duodenal ulcer he has no fears of cancer, and you should also explain to him that many a greater or lesser man, including laborers or business executives, take their thermos bottles with them to work and take milk as you outline for them. A good plan is to have them take with them on trips or carry in a pocket some of the antacid tablets such as Amphojel or Gelusil which they can handily chew as a substitute for their between-meal milk feedings.

I have borrowed liberally from many sources, especially from Walter Lincoln Palmer, M.D.

Discussion

Dr. Herbert Plass: This is a good paper. It is comforting to reflect that this conservative method of managing peptic ulcer continues to be in vogue in the best circles. However, it makes it difficult to discuss the paper because I cannot disagree with it very much. On one point I should like to add an opinion and it is that many times superficial mucosal erosions are all the evidence which can be found radiologically of ulcer in a patient with clear-cut ulcer type story extending over a period of years. This may be the matter of timing of the x-ray examination in that a real crater might be found at the site of the mucosal erosion if the picture had been taken a week or two later without treatment. Of course I am not referring to gastritis of the common variety.

A second point is that it sometimes is fun to try and predict the type of occupation of an individual who comes complaining of ulcer-like distress. I have a feeling that by and large the ulcer-bearing individual prefers to work for someone else and to report to someone else, and that he is more efficient in doing so than if he has to be the top man. This certainly is not universally true, but I think that the hypertensive type of personality is more likely to be top man, as he is also more likely to be a good salesman.

I would like to emphasize that it is not fair to the radiologist to place on his examination the burden of "ruling out" or excluding ulcer. I do not know what number or percentage of ulcers are not demonstrated by x-ray but should guess that it may be in the neighborhood of five per cent, and in the hands of less skilled radiologists perhaps it is higher than this. One certainly cannot eliminate ulcer, for instance, as a cause of gastrointestinal hemorrhage by x-ray examination. Another point which interests me is that a considerable number of patients who have ulcer, easily demonstrated by x-ray or by the presence of one of the complications of ulcer, have been quite asymptomatic over a long period of time. I believe these people come into a sort of uneasy adjustment with their ulcers, and the indigestion they suffer is so much a part of themselves that they don't regard it as a complaint. Sometimes I can find out about these by asking specifically if anti-acid medications are used or carried daily in the pocket.

I heartily subscribe to Dr. Myhre's emphasis on rest as the primary agent in treating ulcers. I am sure nothing else is more important. Finally, I should like to ask a question, "Why do so many ulcer patients interrupt treatment, discontinue their anti-acids and antispasmodics when they have been told to continue them, and blandly turn up a month later having the same kind of distress and not knowing what to do about it?"

Dr. John Rosenow: I have been asked, as a matter of general interest for those of the audience not having direct contact with the problem of peptic ulcer, to say a few words to summarize some of the related surgical considerations.

At the outset I should like to make a distinction between gastric and duodenal ulcer. The accepted surgical procedures when done for gastric ulcer tend to be easier technically and to give better symptomatic results; the mortality is less, and there are fewer postoperative complications. The complication of anastomotic ulcer is rare following resection for gastric ulcer; this is not the case with duodenal ulcer.

The one great distinction between the two types of ulcer that must influence one's thinking in regard to gastric, as opposed to duodenal, ulcer is the question of malignant potentiality. Malignancy in duodenal ulcer is extremely rare. On the other hand, a fair summary of the experience in the literature, I think, would be to say that ten per cent of apparently benign gastric ulcers are actually malignant. I came across an interesting statistical comparison of the surgical versus the medical treatment of gastric ulcer in the new book by Moore and Harkins (Moore, H. G., Jr. and Harkins, N. H.: The Billroth I Gastric Resection. Boston: Little, Brown and Co., 1954). This contains statements that seem surprising but actually represent a reasonable summation of the figures appearing in the literature. Let us take two groups of one hundred cases each. One group will be treated medically, and the other will be treated surgically. First the surgical group—six patients will have carcinoma and six of them will die; two of the total series will die from operation, and nine patients will have disabling postgastrectomy symptoms. Thus a total of seventeen of the surgical patients will not be benefited (including eight deaths) and eighty-three will be benefited. In the medical group, all ten of the carcinoma patients will die. Twenty of the rest will have difficulty of a serious nature in the form of intractability, hemorrhage, perforation or obstruction, and about two of these twenty will die, so a total of thirty of the medical patients will not be benefited (including twelve deaths) and seventy will be benefited.

In considering the general indications for surgery in peptic ulcer, bear in mind that the following indications apply equally well to both gastric and duodenal ulcers, over and above the special consideration of malignant potentiality in those of the gastric variety. On the question of *perforation* there is pretty widespread agreement that the treatment of choice is simple closure of the perforation. However, in recent years there is a good deal of writing being done in this country advocating resection in these people; most men are hesitant to accept this. I think that perhaps in the patient who has been seen early, who is in excellent general condition, and who has had serious trouble with an ulcer for a long time in the past (and therefore might be expected to have difficulty in the future), resection should be considered. *Obstruction* is another generally accepted indication for surgery, almost always resection. But I would like to interpose here a word of caution. All apparent obstruction is not true obstruction, and the patient should have the benefit of hospital care of the medical variety—thorough and with the attention to detail so ably brought out here tonight by Dr. Myhre. In many cases the obstruction will be on the basis of spasm or edema, and these will relent under proper medical care.

As regards *hemorrhage*, there is some difference of opinion, there being all gradations of opinion from those who say all massive bleeders should be operated upon at once, to those who say that practically no one should ever be operated upon for hemorrhage. A few points deserve emphasis. First, bear in mind that the indication is massive hemorrhage, not just hemorrhage. The vast majority of hemorrhages will cease under adequate medical management. The surgical literature is full of work on massive hemorrhage, and I think that the things that are being written pertain to all types and degrees of hemorrhage. The decision as to whether to operate or not must be individualized. Age enters into it, certainly. Perhaps in the older patient who cannot be kept stabilized with 500 cc. of blood every six to eight hours, surgery should be the treatment of choice. In one's thinking on this matter, it is very easy (and I have heard this line of reasoning more than once) to say—"Well, the mortality for resection is only two to three per cent." In the face of massive hemorrhage, the mortality is not two to three per cent but more likely in the neighborhood of ten to fifteen per cent.

Our fourth usually accepted indication for surgery is *intractability*. And here there come about some of the greatest discrepancies in opinions over the country. I think we should remember that surgery for peptic ulcer, although occupying a very valuable place in our therapeutic armamentarium, is no glittering panacea. Gastric resection is, after all, when one really thinks about it, a crude, barbaric assault on the human body. And it is irrevocable. It is in this group of cases with so-called intractability that the proper, really thorough, medical treatment as outlined by Dr. Myhre can make a big difference. In the course of my training, I had a rather interesting chance to compare different ways of handling this problem.

At the hospital where I interned, a chief of one of the medical services had been associated with Dr. Sippy for years, and his thinking and influence affected the treatment of ulcer at this hospital quite strongly. The medical treatment of ulcer was extremely thorough and meticulous, and few patients came to surgery because of intractability alone. Then, when I entered upon my surgical graduate work at another institution, I had some work during that time in the medical sections. I was quite impressed in a not entirely agreeable way with the difference as to medical treatment of ulcer that was sometimes evident. The treatment of ulcer does not consist of giving the patient a diet form, chatting hastily with him as to the great importance of taking it easy, and giving him about ten prescriptions, and writing his doctor. I am sure that many patients over the country as a whole who are subjected to surgery on the basis of intractability would get by on medical treatment of the thorough type described to us tonight.

After all, there is about a five to ten per cent incidence of serious "dumping" of a disabling type after gastric resection, as well as other troubles. You'd rather not have the postgastrectomy patient coming back to you, and saying, "Ye gods, give me back my ulcer." In this connection, I think a rather forthright statement of a preceptor of mine at one stage in my training might well be quoted, namely, that for a patient to be advised to have surgery (in the absence of perforation, hemorrhage, or obstruction), he felt that the patient should have had "one h—l of a lot of trouble." My own personal feeling, had I a troublesome duodenal ulcer, without other complication, about having surgery would be about along those lines—that I'd have to have "one h—l of a lot of trouble."

Dr. Walter Ude: It has been a privilege to hear this splendid paper. The essayist is to be complimented. He has not only given us a complete analysis of the problem in hand, but has also outlined a program of management and therapy which indicates a wide personal knowledge and experience.

A careful and complete radiological examination of the upper gastrointestinal tract plays an important part in the study of patients suspected of ulcer. The fact that the radiological examination should not be the primary procedure to be placed ahead of a careful clinical study is self-evident, but is too often ignored. Certain limitations, which we cannot deny, make it impossible to always "rule in" or "rule out" an ulcer. For instance, we are limited in the extent of the examination in the presence of gross hemorrhage, or in the presence of marked debility from other causes. The case may be referred after a prolonged therapeutic management which may have considerably modified the findings. The ulcer may also be so located that it can be demonstrated only with great difficulty, often in a region where it is not accessible to palpation. A close co-ordination, therefore, of the clinician's findings and the radiologist's examination will yield far better results than the performance of the radiological examination as a routine procedure without direct guidance by the clinician. This brings us back to the age-old admonition that the request for the examination should bring with it this guiding information. Without it the radiologist attempts to get what information he can from the patient while he does the examination, a procedure which certainly cannot compete with the analysis of the clinician.

Permit me to discuss briefly difficulties encountered in four distinct regions of the upper portion of the gastrointestinal tract:

1. Hiatus hernia may be readily demonstrated in the routine examination, but at times is not so readily detected. In my experience, the shortened esophagus with hiatus hernia is best shown by studying the lower end of the esophagus in the prone oblique position during the ingestion of barium suspension through a drinking tube. This method is more successful than an attempt to demonstrate hernia in the Trendelenburg position. Ulcer in the herniated portion of the stomach may be obscured by the barium suspension, but often is clearly in evidence. It should always be kept in mind in cases of hiatus hernia.

2. The high, posterior wall of the stomach is a region where ulcer may be easily overlooked, especially in the sthenic individual.

3. Prepyloric ulcer, either on the posterior wall or on the lesser curvature, may be lost in prominent mucosal folds or obscured by peristaltic activity which may seem to obliterate a suspicious fleck of barium retention. Here, compression spot films with demonstration of mucosal pattern are of great help. If ulcers in this area fail to improve or even seem enlarged after therapeutic management they must be considered as questionably malignant, even though all other findings point toward benign ulcer.

4. Postbulbar ulcer of the duodenum is frequently the cause of silent bleeding from the upper gastrointestinal tract. Our pathologists have impressed us with the importance of finding these ulcers. Penetration directly into the pancreaticoduodenal artery may lead to fatal bleeding, and thus the pathologist will find the ulcer. The radiologist should be just as keenly interested in this region of the duodenum as he is in the duodenal cap. If there is persistent spasm and marked change in the mucosal pattern, a presumptive diagnosis of hidden postbulbar ulcer should be entertained as a working diagnosis, even though a definite crater cannot be found. Where such ulcers are of relatively short duration, the spastic contracture may completely hide the crater. Later

re-examination, often after only a few days, may visualize the crater.

We should not hesitate to re-examine a patient if there is the least doubt as to the findings, or if the clinician is not satisfied that the problem has been solved. We frequently recall a patient because of some suspicious finding on routine films, or the presence of hypersecretion or food retention in the stomach. We do not hesitate to examine in the presence of active bleeding, but avoid deep palpation or compression.

Let me again emphasize the necessity of a close co-ordination of the work of the clinician and the radiologist. Such co-operative effort yields dividends.

Dr. R. S. Ylvisaker: I enjoyed Doctor Myhre's paper very much. In my opinion his excellent summary indicates to us especially the main details which go into good medical care of the peptic ulcer patient. The importance of the subject of peptic ulcer is well known to all of us, and it is also indicated by the frequency with which many phases of this subject are covered in the annual meetings of the American Gastroenterological Association. Dr. Anton Carlson once remarked at one of these meetings that the meeting of the American Gastroenterological Association might be referred to as the "Annual Symposium on Peptic Ulcer."

I believe the main point that Doctor Myhre stressed in his paper was the need for a meticulous attention to detail in both the accurate diagnosis and the treatment of peptic ulcer. One is often discouraged with the laxness with which medical treatment is prescribed in this condition. In fact, many papers have appeared in the literature, even by men well respected in their fields who recommend more frequent surgical treatment because of failure of medical management when such management has been anything but careful. There is no question in my mind but that a good ninety-five per cent of peptic ulcers can be cured or well controlled by careful medical management carried out over a protracted period of time.

I would like to comment briefly on a few other points mentioned by Doctor Myhre:

1. The well-known dictum of no acid, no ulcer. This is undoubtedly the general rule and the safest guide to follow. In regard to gastric ulcer, any ulcer that appears in the presence of achlorhydria should be considered malignant until proved otherwise. However, I am sure that all of us have had the experience of occasionally finding a benign gastric ulcer even in the presence of a well established achlorhydria.

2. In regard to the incidence of peptic ulcer in hypertension, it is true that the usual case of peptic ulcer is apt to have a low to normal blood pressure and a slow pulse. However, I have recently had several cases of proven peptic ulcer come under my care with hypertension.

3. I cannot accept the position held by some of routinely advising surgery in gastric ulcer, chiefly for two reasons. The first is that by meticulous attention to detail and calling in every possible diagnostic aid, including gastroscopy in suspicious cases, I believe that the error of overlooking malignant ulcers can be dropped down well below the ten per cent mark. In the second place, I frankly do not believe that the results of surgery in cancer of the stomach are good enough to warrant submitting ninety per cent of the people to unnecessary surgery when perhaps only one out of ten of the malignant cases can be cured. Here again, each case must be studied individually and all factors evaluated before a choice of method of treatment is made.

4. In regard to gastric hemorrhage, I believe it is a mistake to routinely transfuse these cases on admission to the hospital. There is evidence to show that immediate transfusion increases the risk of continued bleeding, recurrent bleeding, and even increases the mortality rate. By far the majority of cases of gastric hemorrhage will subside promptly on complete bed rest. The crying need is for closer observation of each case and the use of transfusion only in those in which evidences of shock persist. Later after there is good evidence that bleeding has stopped, if the hemoglobin is low, then it is justifiable to transfuse in order to shorten the period of convalescence and overcome the severe anemia.

Dr. Jay C. Davis: I do not agree with Dr. Myhre that all patients with an ulcer should be hospitalized. There are some patients who can be healed while ambulatory. There are some who respond to treatment faster if they can get away on a vacation out of their own city and completely away from all disturbing factors that may exist in their family life or business.

Psychosomatic factors are very important and until the factors can be discovered and talked over with the patient one may not succeed in curing the patient.

Dr. Ylvisaker stated in his discussion that all peptic ulcer hemorrhages do not need surgery. It is important, however, to remember that slow bleeding over a period of many days may result in an anemia and drop in blood pressure severe enough to cause angina and changes in the electrocardiogram suggesting coronary insufficiency especially in an older patient with coronary sclerosis. A massive hemorrhage with a marked drop in blood pressure may result in such a marked coronary insufficiency that myocardial infarction may ensue without closure of a coronary artery. If the fall in blood pressure and the hemorrhage is massive, or if more than one severe hemorrhage occurs before surgery is resorted to the patient may suffer cerebral damage from anoxia. Degeneration of the kidney tubules may also occur with uremia resulting, or the patient may die in hepatic coma if a damaged liver existed at the time of the hemorrhage.

Why Milliequivalents?

JOHN H. ROSENOW, M.D.
Minneapolis, Minnesota

THE FOLLOWING presentation says nothing new or original. It is an attempt to answer the question posed by the title by giving in as simple a form as possible, some of the information gleaned from the literature about milliequivalents as a system of units. This information is too often found in journals not readily available, or in highly technical and complicated form.

What is a milliequivalent? The chemical potency of a substance in solution depends on the amount of it present by weight, the substance's atomic weight and the substance's valence. The comparative potency of the substances in solution can be expressed according to how much hydrogen ion they will neutralize or be equivalent to. The unit of measure in chemistry is the equivalent.

BASE (mEq/L)	
Na^+	142
K^+	5
Ca^{++}	5
Mg^{++}	3
	155

ACID	
HCO_3^-	27
Cl^-	103
HPO_4^{--}	2
SO_4^{--}	1
ORG.AC.	6
PROTEIN	16
	155

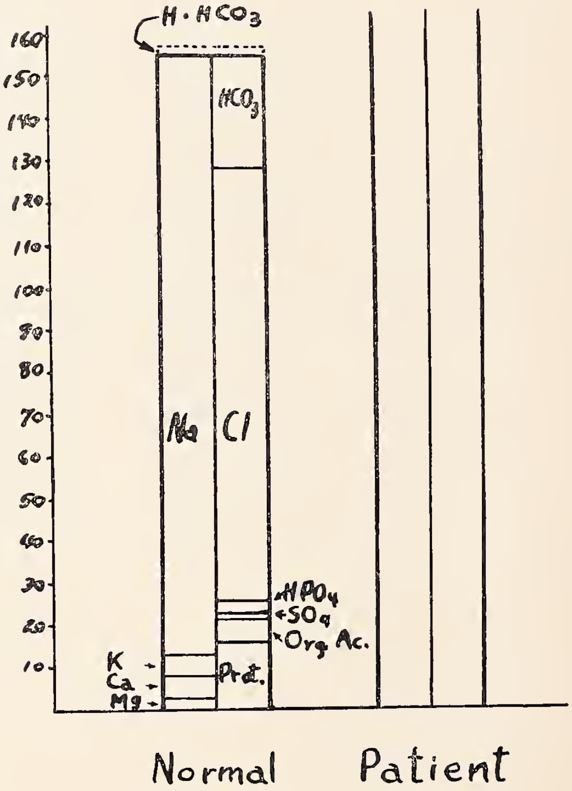

Fig. 1. Acid-base composition of blood plasma.[4]

Definitions

An electrolyte is a chemical substance, which when dissolved in a solution, separates or dissociates into electrically charged positive and negative particles, or atoms, called ions. The positive ions are called cations and the negative ions are called anions.

An equivalent is the weight of an ion, which in neutralization reactions, is equivalent to, or will neutralize one gram-atom of hydrogen. For example, one atom of chlorine will neutralize one atom of hydrogen since they are of the same valence, a valence of one. Therefore, since the weight of one atom of chlorine expressed in grams is 35.5, and that of hydrogen is one, then 35.5 grams of chlorine will neutralize or be equivalent

---

Abridgement of inaugural thesis presented before the Minneapolis Academy of Medicine, March 16, 1953.

to one gram of hydrogen. If the amount of chlorine is double, then we have two equivalents of chlorine present, and so on. Again, for example, a single atom of calcium, having a valence of two, will combine with or neutralize two atoms of chlorine. Since the atomic weight of calcium is 40 and that of chlorine is 35.5, then 40 grams of calcium are equivalent to twice 35.5 or 71 grams of chlorine in a chemical solution. Equivalent=(grams x valence)÷atomic weight. Equivalents as units of measure are satisfactory for use in chemistry but not in medicine. In medicine, the amounts of ion dealt with are too small, so the milliequivalent is used, or one thousandth of an equivalent. Milliequivalents are expressed as units per liter, and are abbreviated "mEq" or "meq." Under normal conditions, there are 155 mEq of basic ions (cations), and 155 mEq of acid ions (anions) per liter of plasma. For practical purposes, the sum of the basic ions always equals the sum of the acid ions.

General Remarks

It would seem high time that we stop considering the various electrolytes as so much dead weight measured in ounces on the grocer's scales. We are dealing, in plasma, not with amounts by weight of chemical salts such as NaCl, KCl, and the like, but with separately controlled, independently reacting ions such as Na, K, Cl, and so on. The ions are active elements and we should evaluate them on their chemical activity. To do this and to understand the actual chemistry of fluid balance is to talk in terms of mEqs. It would be folly, for instance, to compare engines solely on the basis of their weight. A more valid and useful comparison is on the basis of their capacity for producing power, i.e., horsepower. One gram of chloride ions in plasma is roughly 100 times as powerful as one gram of protein when measured from the standpoint of chemical combining capacity, and 800 times as powerful osmotically. One gram of sodium in plasma is about 150 times as potent chemically and 1,200 times as potent osmotically as one gram of protein.

The rating of ions in the fluids of the body on the basis of such differing units as milligrams per 100 cc., grams per 100 cc., and volumes per cent, is perhaps like trying to work with fractions having different denominators. It would be impossible to add ⅓, ¼, and ⅛, let us say, if we did not have that very useful echo from grade-school days, the least common denominator. It then becomes simple to add 8/24, 6/24, and 3/24 to get the answer of 17/24. MEqs might be thought of as the least common denominators of fluid balance.

An example of this and of the differing worth of dead weight units and activity units (or mEqs) is readily found in a patient who loses 7.0 grams of chloride and 4.6 grams of sodium in tube drainage. It would be immediately apparent only to a chemist that loss of basic and acid ions is going on equally. If it were stated, as is actually the case, in this instance, that the patient lost 200 mEq each of chloride and sodium, the acid-base significance would be clear. It would also be clear that the relation of the two is high in chloride relative to extracellular fluid composition where the ratio is 142 of sodium to 103 of chloride. He will deplete his chlorides faster than his sodium. The loss of such a solution wholly from extracellular sources would thus lower chloride concentration differentially and produce metabolic acidosis despite the chemically neutral nature of the loss.

Examples of Use of Milliequivalents

Before embarking on the examples, let me call attention to the normal values in Figure 1. The first example is based on the fact that the sum of the basic ions equals the sum of the acid ions. Before the development of the flame photometric method of analysis of plasma, the only way to arrive at a rapid, rough estimate of the electrolyte concentrations, especially that of sodium, was by application of the equality of the acid and base ions, using other more easily obtainable values, such as for HCO_3 and Cl. And where a flame photometer is not available it still can serve, in spite of obvious shortcomings. For it to be valid, we must be able to assume that potassium is normal, and that the acid ions other than HCO_3 and Cl are present in normal amounts, often, of course, not the case.

(R^+ represents the sum of the basic ions other than sodium, and R^- represents the sum of the acid ions other than HCO_3 and Cl.)

$$\begin{array}{lcl}\text{sum of base ions} & = & \text{sum of acid ions}\\ \text{Na} + R^+ & = & HCO_3 + \text{Cl} + R^-\\ \text{Na} + 13 & = & HCO_3 + \text{Cl} + 25\end{array}$$

Now let us say that we have values for HCO_3 and Cl of 23 and 88 mEq/L respectively.

$$
\begin{aligned}
\text{Na} + 13 &= 23 + 88 + 25 \\
\text{Na} &= (23 + 88 + 25) - 13 \\
\text{Na} &= 136 - 13 = 123 \text{ mEq/L}
\end{aligned}
$$

The value for serum protein in mEq could of course be inserted or interpolated in the equation and would increase its accuracy somewhat. This method, while a thin reed to lean on, can be used if the exceptions and inaccuracies are kept in mind, with an occasional check by the older, time-consuming direct chemical determination of sodium.

Let's take up another oversimplified example. One could estimate roughly the amount of solution necessary to return the electrolyte concentration to normal. If we assume that the extracellular fluid volume is 20 per cent of the body weight (or body weight÷5), the following formula could be used as an approximate guide:

$$
\text{Total amount of ion needed} = \frac{\text{Pt's wt. in kg.}}{5} \times \left\{ \begin{matrix}\text{normal value}\\ \text{of ion in}\\ \text{mEq/L}\end{matrix} - \begin{matrix}\text{pt's level}\\ \text{of ion in}\\ \text{mEq/L}\end{matrix} \right\}
$$

Let's run through that with an example of a man weighing 175 pounds, who has a sodium of 132 mEq/L, remembering, of course, that to convert pounds to kilograms, divide by 2.2. His weight is thus 175÷2.2=80 kg.

$$
\text{Total needed} = \frac{80}{5} \times (142 - 132) = 16 \times 10 = 160 \text{ mEq}
$$

Physiological saline contains 154 mEq of sodium per liter, so one liter would give the approximate amount, theoretically, which would restore the sodium to normal.

Now for a more complicated example. Given a patient who has lost 3 liters of body fluids by suction drainage. Her normal weight is 114½ pounds (52 kilograms). She has the following values for electrolytes, which are converted using the factors found in Table I,

CO_2.......... 50.6 vol.% x 0.45 = 23 mEq/L
Cl (as NaCl) 550.0 mgm. per 100 cc. x 0.171 = 94 "
Protein....... 7.4 Gm. per 100 cc. x 2.43 = 18 "
Sodium .....298.0 mgm. per 100 cc. x 0.435 = 130 "

The patient's three liter loss of fluid, for the purposes of this example, is presumed to come from the extracellular fluids. So we first figure the normal amount of extracellular fluid for this patient and then subtract the loss,

$$
\begin{array}{rl}
52 \text{ kg} \div 5 = 10.4 & \text{liters, her normal extracellular fluid} \\
-\ 3.0 & \text{liters, loss} \\
\hline
7.4 & \text{liters, extracellular fluid after loss (a rather broad assumption)}
\end{array}
$$

$$
\begin{array}{lrr}
\text{Na}\begin{cases}\text{Normal} \\ \text{After loss}\end{cases} & \begin{matrix}10.4 \times 142 = \\ 7.4 \times 130 = -\end{matrix} & \begin{matrix}1477 \text{ mEq of Na}^1 \\ 962 \quad \text{"} \quad \text{"} \quad \text{"}^2\end{matrix} \\
 & & \overline{515 \quad \text{"} \quad \text{"} \quad \text{"}^3}
\end{array}
$$

[1] Total amount normally present
[2] Amount present after loss of 3 liters
[3] Of Na which have been lost

$$
\begin{array}{lrr}
\text{Cl}\begin{cases}\text{Normal} \\ \text{After loss}\end{cases} & \begin{matrix}10.4 \times 103 = \\ 7.4 \times 94 = -\end{matrix} & \begin{matrix}1071 \text{ mEq of Cl}^1 \\ 695 \quad \text{"} \quad \text{"} \quad \text{"}^2\end{matrix} \\
 & & \overline{376 \quad \text{"} \quad \text{"} \quad \text{"}^3}
\end{array}
$$

[1] Total amount normally present
[2] Amount present after loss of 3 liters
[3] Of Cl which have been lost

It remains to pick the repair solutions, which can be done without too much difficulty when we know the mEq content of the various available solutions (Table II).

As to chlorides—we see from the table that normal saline has 154 mEq/L of chloride, so to supply the deficit of 376 mEq, we need 376÷154 =2.4+liters. This amount of saline will supply us with the same amount of sodium, or 376 mEq. So we are left with 515—376=139 mEq of sodium to supply in some other way. Preferably we would like a solution having the sodium in combination with an acid ion that is easily metabolized, in order not to increase unduly the acid ions. Sixth molar sodium lactate is an excellent solution for this purpose. How much is needed? A liter of this solution, according to the table, contains 167 mEq of sodium, so we need 139÷167=832 cc. of sixth Molar sodium lactate.

For practical purposes, then, we would need about 2½ liters of saline and 800 cc. of sixth Molar sodium lactate. This would give us a little more total volume of fluid than we need. These calculations are for replacement of an existing immediate deficiency and do not provide for replacement of basic requirements such as losses through lungs, skin, obligatory volume needed by the kidneys and the like. The extra fluid we gave in our example could be reckoned in when those basic requirements are being calculated.

I cannot emphasize too strongly that the foregoing examples are purely for the purposes of illustration. They are not in any way advanced as specific guides in solving fluid-electrolyte problems. There are no pat, fool-proof rigid formulae that can be applied to all cases. But with the use of milliequivalents, at least such problems can be approached with some degree of intelligent understanding, and they may well lose some of their weird, cabalistic, mysterious aspects, and may become, while not always exactly simple, at least possible of rational solution.

TABLE I. NORMAL ELECTROLYTE VALUES—CONVERSION FACTORS

	Normal (mgm/100 ml)	×	Factor	=	Normal (mEq/L)
Na^+	317—340		0.435		137—148
K^+	16—21		0.257		4.1—5.4
Ca^{++}	9—11		0.5		4.5—5.5
Mg^{++}	1.2—2.4		0.82		1—2
HCO_3^- (CO_2 vol. %)	55—75	(or ÷2.22)	0.45		25—34
Cl^- (as NaCl)	585—645		0.171		100—110
(as Cl)	352—389		0.282		100—110
PO_4^{--}	3—5		0.58		1.7—2.9
SO_4^{--}	1.6—2.4		0.625		1.0—1.5
Protein (Gm. %)	6.5—8.0		2.43		16—19

$$\text{Concentration (mEq/L)} = \frac{\text{Concentration (mgm/100 ml)} \times 10}{\text{atomic weight}} \times \text{Valence}$$

$$\text{Conversion factor*} = \frac{10}{\text{atomic weight}} \times \text{Valence}$$

*does not apply to HCO_3, PO_4, and protein.

TABLE II. ELECTROLYTE CONTENT OF INFUSION FLUIDS (mEq/L)

Fluid	Na	K	Ca	Cl	Effective CO_2	NH_3	Mg	HPO_4
NaCl 0.9%	154.0			154.0

Travert 10%—KCl 0.3% in water (Baxter)		40.0		40.0				
Travert 10%—KCl 0.3% in 0.45% NaCl (Baxter)	77.0	40.0		117.0				

Discussion

In the field of fluid-electrolyte balance, a vast amount of research is being done, and major advances and changes in concepts are taking place. The work is, and of necessity must be, done in terms of milliequivalents. The article in the literature on this subject which reports in other terms than milliequivalents is rare indeed. If we wish to have an intelligent understanding of what is being done, and want to put it to enlightened practical use, we should be familiar with the language in which it is written, so to speak.

For those of us who do not work exclusively in the so-called teaching institutions, the habit of thinking and working in terms of milliequivalents is made difficult to acquire by the fact that most hospital laboratories report electrolytes in the older system. It is suggested that the advent of the newer system might be hastened if hospital laboratories were asked routinely to report all electrolyte values in both systems for a time, with the eventual end in view of reporting only in milliequivalents. The conversions can be done far more easily in the laboratory, from prepared tables and graphs, without the necessity for actual calculations. Thought might be given to the provision in charts of a special electrolyte form, either separately or as part of the regular laboratory sheet; part could be a form for the reporting of the patient's values in both systems, and part could be a table of normal milliequivalent values.

It is unquestioned that in the ordinary case, all of this isn't too necessary. But the occasional complicated problem almost demands use of the milliequivalent system for intelligent handling.

Summary

It is hoped that the foregoing presentation may in some small measure help to answer the question posed by the title by bringing together from the literature some items of interest, edification, illustration and justification regarding the use of milliequivalents.

REGULAR CORPS EXAMINATION FOR MEDICAL OFFICERS

A competitive examination for appointment of Medical Officers to the Regular Corps of the United States Public Health Service will be held in various places throughout the country on June 7, 8, and 9, 1955.

Appointments provide opportunities for career service in clinical medicine, research, and public health. They will be made in the ranks of Assistant and Senior Assistant, equivalent to Navy ranks of Lieutenant (j.g.) and Lieutenant, respectively.

Entrance pay for an Assistant Surgeon with dependents is $6,017 per annum; for Senior Assistant Surgeon with dependents, $6,918. Provisions are made for promotions at regular intervals.

Benefits include periodic pay increases, thirty days' annual leave, sick leave, medical care, disability retirement pay, retirement pay which is three-fourths of annual basic pay at time of retirement, and other privileges.

Active duty as a Public Health Service officer fulfills the obligation of Selective Service.

Requirements for both ranks are U. S. citizenship, age of at least twenty-one years, and graduation from a recognized school of medicine. For the rank of Assistant Surgeon, at least seven years of collegiate and professional training and appropriate experience are needed, and, for Senior Assistant Surgeon, at least ten years of collegiate and professional training and appropriate experience are needed.

Entrance examinations will include an oral interview, physical examination, and comprehensive objective examinations in the professional field.

Application forms may be obtained by writing to the Chief, Division of Personnel, Public Health Service, Department of Health, Education, and Welfare, Washington 25, D. C. Completed application forms must be received in the Division of Personnel no later than May 6, 1955.

Clinical Aspects of Fluid and Electrolyte Management

J. H. STRICKLER, M.D., and CARL O. RICE, M.D.
Minneapolis, Minnesota

IN THE PRACTICAL day-to-day management of a patient on total, or even partial, artificial alimentation it would be ideal if one could order a uniform or standard intravenous feeding solution. However, in illness and stress every patient presents a variation that must be accurately dealt with.

Fluid, electrolyte, nitrogen and caloric needs require an assessment of basic needs, an estimate of deficits to be repeated and accurate information on losses that are occurring.

Adequate caloric and nitrogen intake is difficult to achieve by intravenous solutions unless all of the nutritional elements are utilized, and therefore the basic solution should contain 5 or 6 per cent amino acids to provide nitrogen in 10 to 15 per cent invert sugar or fructose to provide the carbohydrates, and 5 to 7.5 per cent alcohol to provide the additional calories which are ordinarily supplied by fat. Such a solution contains 1000 calories per liter and is capable of supplying at least 100 per cent of energy requirement without exceeding the fluid needs. All the fluid requirement of any but an anuric patient should be supplied in this form.

In the sick individual the fluid and electrolyte needs may vary greatly from the average normal. There is, therefore, no substitute for frequent, detailed analyses of the chemical levels and of careful calculation of balances determined from body fluid and excretion levels. With this information one can then more accurately order the volume of fluid and quantity of electrolytes as they are needed from day to day. The basic solution of amino acids and invert sugar or fructose must be one of low sodium, potassium and chloride content so that calculated quantities may be added to accommodate the requirement of the patient.

Such electrolyte additions may be easily made by injecting them into the basic solution from stock concentrates made up in sterile vials by a pharmacist. In this manner the physician can avoid ordering a liter of this and a liter of that—a method certain to be deficient in one or more aspects of nutrition.

At the outset a base line must be determined. Weight, hemoglobin, hematocrit, carbon dioxide, chloride, BUN, protein, urine specific gravity, and usually serum sodium and potassium are sufficient. The state of hydration and deviations from electrolyte equilibrium are then evident. If a deficit is present it is obvious that the balances attained on succeeding days must be on the positive side until repletion is achieved.

Fluid balance can be maintained only by careful attention to the following.

1. An accurate intake and output record must be kept. In this regard meticulous endeavor by the nursing staff is indispensable. An inlying catheter may be required in seriously ill or incontinent patients. Nasal suction should always be collected into a trap bottle.

2. Calculation or estimation of insensible water loss. The Darrow formula (adult) of 44 cc. insensible water loss for each 100 calories metabolized is quite easily calculated from the DuBois chart of the Lilly Co. slide rule for diabetic diets. Regardless of the caloric intake, an individual must satisfy his energy demands. From height, age, weight and sex factors on the DuBois scale one can find the caloric requirement. For normal bed activity and specific dynamic action the factor of basal calories plus 40 per cent is employed. To this factor 8 per cent is added for each degree of

---

Presented by title as thesis before the Minneapolis Academy of Medicine, March 16, 1953.

fever. The wide variance in insensible fluid loss is demonstrated by the following examples.

(A) A 6′, 200-pound man, thirty-five years old, with temperature of 102.6°
Basal = 2000 calories
Bed activity) + 40% = 800 calories
and SDA)
3° fever × 8 =)
+ 24% ¼ of 2000) = 500 calories
3300 calories requirement
33 × 44 = 1452 cc. insensible water loss per 24 hours.

(B) 5′ 2″ 100 pound woman, thirty-five years of age, with normal temperature
Basal = 1240 calories
Bed activity) + 40% = 500 calories
+ SDA)
17.4 × 44 = 766 cc. insensible water loss.

TABLE I. BLOOD ELECTROLYTES IN PATIENT DEVELOPING HYPOCHLOREMIC SHOCK AFTER HYDRATION

	Adm.	4th Day	4th Day +3 Hr.	5th Day	11th Day
Hematocrit	56	46		47	36
CO_2 comb. power mEq/L	31	46	30	31	27
Chloride mEq/L	97	71	103	86	98
BUN	15				72
Sodium mEq/L	149				156
Potassium mEq/L	3.8				2.3
Cumulative Na bal. mEq.		+23			+739
Cumulative K bal. mEq.		+2.1			+211
Cumulative Cl bal. mEq.		+49			+736
Cumulative Fluid bal. cc.		+804			+2449
		Day of shock			

TABLE II.

	Number of Determinations	Volume cc	Average mEq/L		
			Sodium	Potassium	Chloride
Gastric suction* No oral intake	68	795	64	9.7	87
Gastric suction* Oral intake av. 792 cc.	108	1267	45	6.1	89
Gastric suction after gastrectomy. Oral intake average 269 cc.	86	603	70	7.5	63
Urine	518	1404	64	36.0	39
Bile	51	195	136	4.7	100

*Gastrectomy patients not included.

From these examples one can see at a glance that reliance upon estimate of, say, 800 to 1000 cc. insensible water loss would lead to serious aberration in fluid balance before many days had passed.

3. Daily body weight, when determined carefully with proper apparatus for bed patients, is an ideal method of following fluid balance. Before dehydration becomes clinically evident a 6 per cent loss of body weight has occurred (9 pounds in a 150-pound man). When the measured fluid output and calculated insensible water loss are subtracted from fluid intake and this figure checked against body weight, one has a fairly accurate evaluation of a patient's fluid status.

Electrolyte Balance.—Reliance upon a normal or average behavior of electrolyte physiology may lead to disaster. Laboratory determinations of serum levels and excretion quantities provide a far greater safety.

1. The state of hydration has a profound effect upon the electrolyte status for overhydration leads to dilution of electrolytes and dehydration causes serum electrolytes to rise above normal levels.

Since the symptoms of electrolyte disturbances are direct results of the serum concentration levels rather than total body quantities, it is important to realize that an untreated patient who has suffered loss of both water and electrolytes may, under certain circumstances, have an entirely normal serum electrolyte pattern and therefore no clinical symptoms of electrolyte deficit. It is such a patient who, on repletion of too much water in proportion to electrolytes, will surprise the physician when he develops severe symptoms of mineral deficit. Conversely, a patient who has been overtreated (usually by saline solution) may exhibit symptoms of hyperconcentration if, in recovery of edema, he loses water faster than electrolytes.

Thus, one must gather as many facts as possible on the state of hydration in order to properly evaluate the significance of serum electrolyte determinations.

To illustrate, let us assume a hypothetical case of dehydration and consider the chloride ion:

Admission: Hematocrit, 56, chloride 97 mEq, weight 50 kg.
Normal: Hematocrit, 40, chloride 104 mEq

Since the chloride level is determined from extracellular fluid space, and since this space is 20 per cent of total body, take 20 per cent of 50. = 10 liters (this patient's normal extracellular fluid volume).

Hematocrit of 56 — 40 = 16. 16/40 = 40 per cent less fluid than normal.
40 per cent × 10 liters = 4 liters deficit.

To calculate predicted serum levels in re-hydration, a proportion may be set up.

Pt. hemat.:pt. cl.::normal hemat.:expected cl.
56:97::40:cl′
56 cl′ = 3880
cl′ = 69 mEq/L

Thus 69 mEq/L would be the chloride level in the serum if the 4-liter water deficit were replaced without giving any chloride ion.

To calculate the total existing chloride deficit in a 10-liter space (pt. normal):

69 × 10 = 690 mEq cl actually present on admission.
104 × 10 1040 mEq cl normal chloride content of 10 L. space.
1040 — 690 = 350 mEq cl calculated total deficit of chloride in extracellular space.

In order to adjust to shifts that may occur and to permit re-evaluation in the course of repletion, a wise plan is to replete the calculated deficit over a three-day period. Therefore, in this example, the total deficit of 350 mEq cl. and 4 liters of water are divided by 3, thus, 117 mEq cl. and 1333 cc. of water are added to each day's chloride and fluid requirement for three days.

TABLE III. TABLE OF AVERAGE URINE EXCRETION RATIO OF SODIUM TO CHLORIDE

	300 Determinations mEq/L		
	Pre-op.	Post-op.	Total
Sodium	90.8 mEq (5.3 gm.)	37.0 mEq (2.2 gm.)	62.6 mEq (3.7 gm.)
Chloride	86.7 mEq (5.1 gm.)	44.3 mEq (2.6 gm.)	64.1 mEq (3.8 gm.)

TABLE IV. EXAMPLES OF DEVIATIONS FROM THE AVERAGE

	Na:Cl Urine Excretion Ratio. Daily Determinations (mEq/L)

	Daily K Bal.		−41.0	−39.0	−3.0	−27.0	−89.0	+124	+56	

The serious drop in serum electrolyte concentration that follows rehydration without calculating the anticipated dilution and without adequate electrolyte administration to prevent dilution may be exemplified by data from an actual case.

This patient had partial pyloric obstruction for two months. Her general condition was quite satisfactory and dehydration was not apparent clinically. Fluid administration was, in the main, without electrolytes. On the fourth day profound shock appeared. The blood pressure was near zero until Levophed (nor-epinephrine) was given. Such shock has been called "hypochloremic shock" but may well be a more general condition of hypo-osmolarity.

When shock state was discovered, the patient was given 3150 cc. of fluid containing 642 meq. sodium, 656 meq. chloride, 23 meq. ammonia, 33 meq. potassium and 33 meq. phosphate, and after the first liter, Levophed was no longer needed. In such a critical case the usual rule of cautious repletion over a three-day period was deferred and a 3 per cent concentration of sodium chloride was used in the first 500 cc. It may be noted that a normal chloride level was attained in three hours. This case also exemplifies the rise in BUN in the presence of severe electrolyte imbalance.

This elevation may occur as it did in this case in spite of a satisfactory urine volume.

It should be noted that the serum potassium dropped to an even lower level in spite of a positive balance.

The strongly positive sodium balance no doubt is a result of giving too much sodium chloride to correct what should have been mainly a chloride deficit (pyloric obstruction). A hypernatremia of 156 mEq/L approaches a serious level. More ammonium chloride perhaps should have been given, but the ammonia ion is extremely toxic if not immediately converted to urea by the liver. If this concern is justified, then in cases of shock a rapid and safe means of pure chloride administration does not exist.

Blood and extracellular space measurements are more accurately determined by Evans Blue and inulin methods, but the hematocrit is more generally available and is reasonably helpful if anemia or blood loss do not interfere with accuracy.

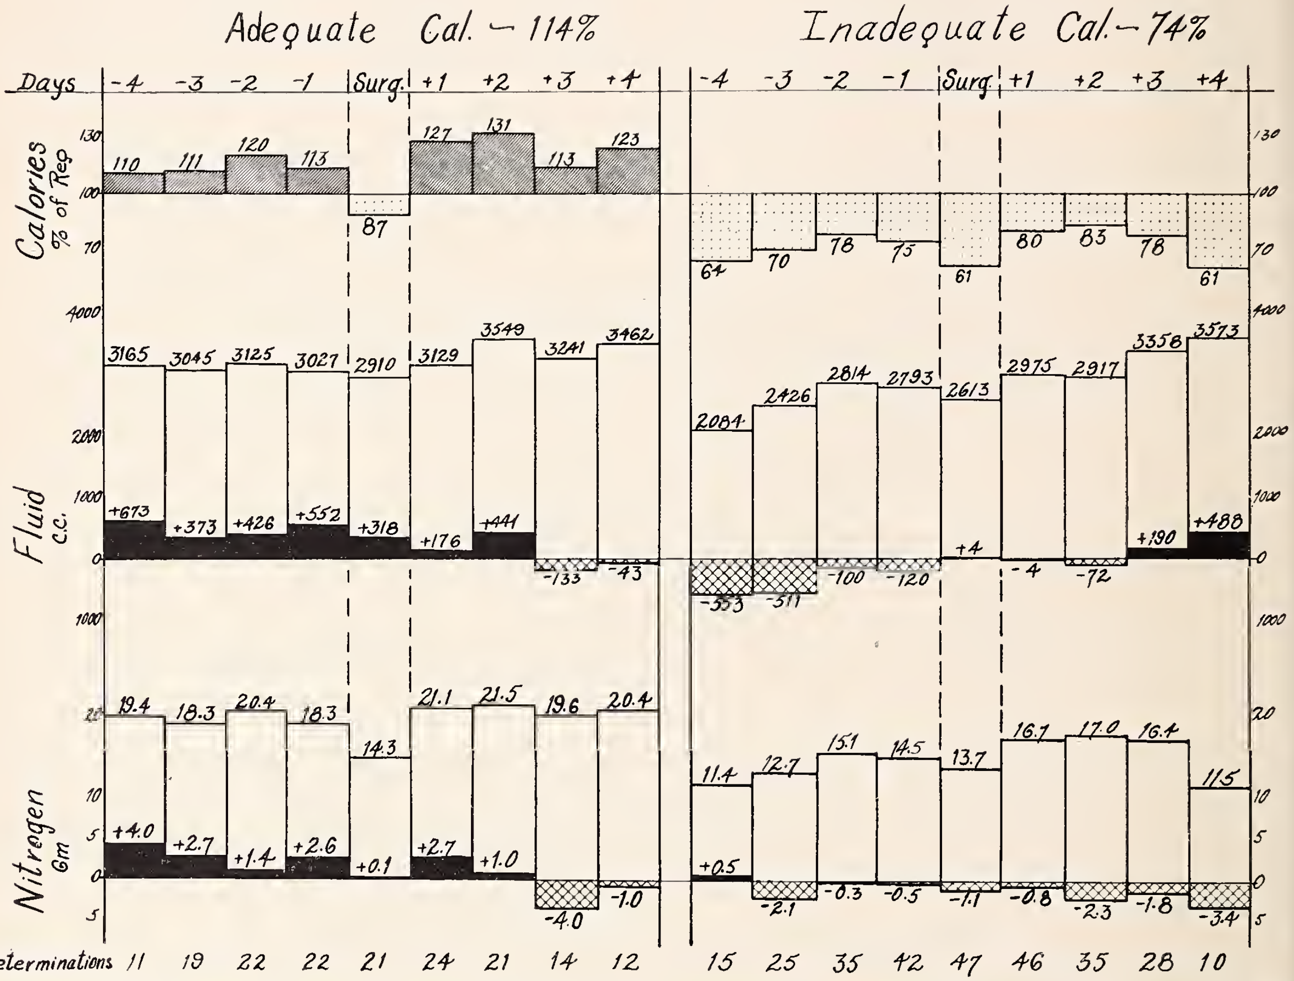

Fig. 1. Intake from zero upward; output from intake line downward. Balance indicated by +black and —cross hatch. Balance studies on 102 patients averaging five days study for each patient. Comparison between the adequate and the inadequate groups reveal a more positive nitrogen balance associated with a better caloric intake. In both groups the catabolic effect of surgery is observed in the postoperative period.

Only the quantity of extracellular ions such as sodium, chloride, etc., are amenable to calculation by this method. Potassium deficit must be estimated by other means.

2. Electrolyte losses that occur from day to day in the hospital must be carefully collected. Urine, gastric suction and bile may, depending upon case urgency, be pooled into one to three day output collections.

Although rather extreme variations occur in gastric suction and particularly in urine electrolyte content, average values are of some use as a starting point.

From several hundred determinations we have compiled the following chart on average electrolyte concentrations in various body fluids and excreta.

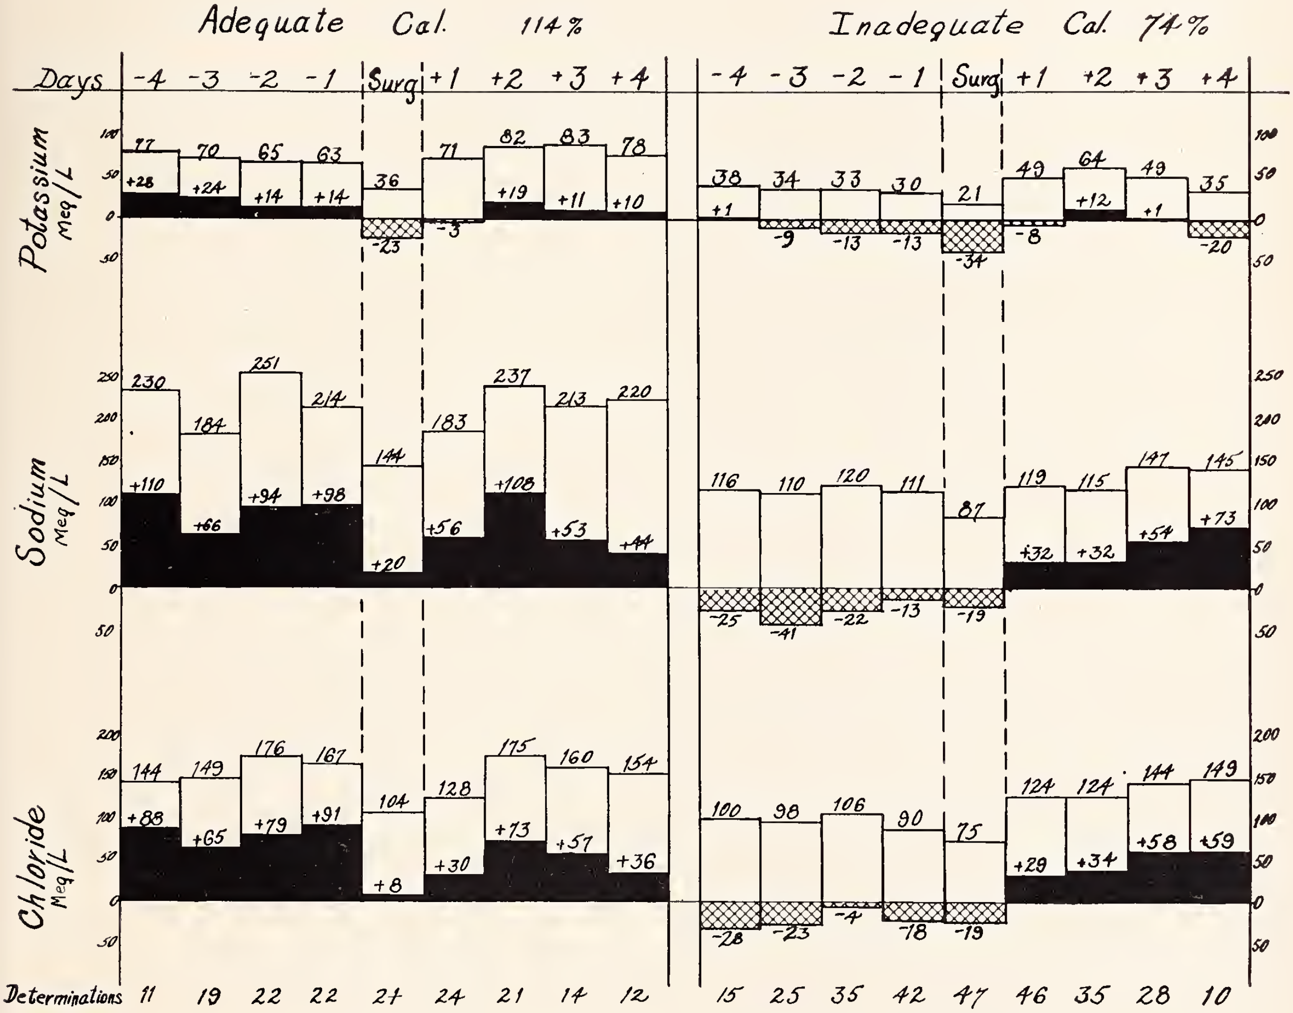

Fig. 2. Intake from zero upward; output from intake line downward. Balance is shown by +black and —cross hatch. Electrolyte balance studies upon the same group of patients in Figure 1. The potassium shift toward negativity from the preoperative to the postoperative period is not as great in the adequate calorie group. The sodium and the chloride ions exhibit an obvious difference between the adequate and the inadequate calorie groups. The intake of these ions does not vary sufficiently within each calorie group, i.e., between pre- and postoperative phase, to explain the variation in pre- and postoperative behavior between adequate and inadequate calorie groups.

In the average surgical patient sodium is excreted in an amount equivalent to the chloride excretion. The simplicity of urinary chloride determinations makes the method quite attractive. However, many physiologic influences may produce extreme variations in any given patient. Therefore, in dealing with an individual case it is unsafe to presume a 1:1 ratio between chloride and sodium. True sodium and chloride determinations should be obtained from the specimen.

The average surgical patient has a urine sodium to chloride ratio of 1:1.

The marked drop in sodium and chloride output in the postoperative period should be noted and taken into consideration in postoperative electrolyte administration.

Marked deviations from the average 1:1 excretion ratio frequently occur both from one patient to another and from day to day in the same patient.

3. Balance data are particularly valuable in regard to the potassium ion. The main concern in surgical patients is directed toward prevention of hypopotassemia and toward correction if it has already occurred.

Since less than 2 per cent of total body potassium is located in the extracellular fluid, a relatively large depletion (up to 50 per cent) of body potassium occurs before the loss is reflected in the serum potassium level. Although clinical symptoms attributed specifically to a low potassium occur only after the serum level dropped at least one milliequivalent below normal, there are many undesirable changes of cellular physiology aready under way. The presence of a strongly negative potassium balance permits a one-day to three-day prediction of drop in serum potassium level.

CHART I. SHEET FOR RECORDING DATA

Name		Age	Wt.		Diagnosis:

	Cl (100-106) mEq/L								
	K (3.8-5.2) mEq/L								
	NA (137-147) mEq/L								
	Sugar (80-120) mg. %								
	BUN (8-20)								
	Protein A/G (6.7-8.4)								

4. Shifts of electrolytes within the body may be detected by studies of the balance data.

For example, a patient who had received an excess of sodium exhibited the following balance findings in a combined three-day study.

Sodium balance + 800 meq.
Serum sodium rose from 158 to 170 meq/L
1/5 (extracellular fluid) × 65 (body wt. in kg.) = 13 liters extracellular fluid.
170 — 158 = 12 meq/L increase of sodium
12 × 13 = 156 meq. in extracellular space.
800 — 156 = 644 meq. of extra sodium located elsewhere than the extracellular fluid space.

Caloric Balance.—An adequate caloric intake appears to have an influence upon the equilibrium of electrolytes as well as nitrogen. It is reasonable to assume that if a patient's weight is maintained while on a sub-caloric diet that a gradual dilution of his system, a water logging, must occur since without meeting caloric requirements tissue loss is obligatory.

Complete balance studies of calories, nitrogen, sodium, potassium, chloride and fluid were recorded on 102 patients, an average of five days for each patient. After correction for urinary loss of calories (sugar), the 102 patients were divided into two groups. One group received 100 per cent or more of caloric requirement and the other group was given less calories. Significance of this material must await completion of statistical evaluation now in progress. However, certain differences between the adequate and the inadequate calorie group are demonstrable in graphic form (Fig. 1).

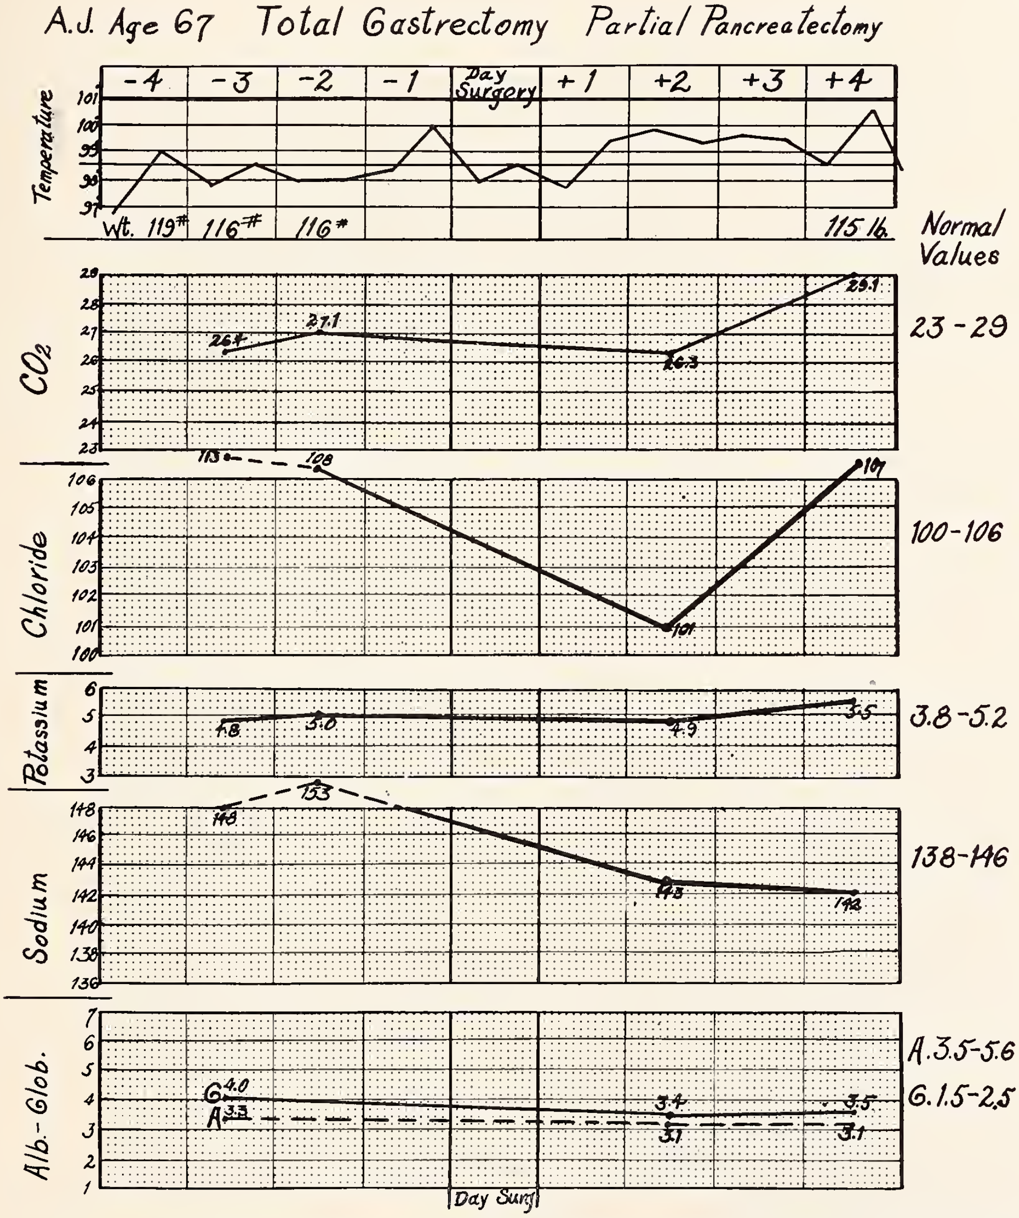

Fig. 3. Blood chemistry studies on a patient operated upon for extensive gastric cancer. Caloric intake averaged 89 per cent of requirement.

An obvious difference in the behavior of the sodium and the chloride ion exists. Even though the intake is not the same in the adequate as in the inadequate calorie group, there is noted a reversal of the preoperative and postoperative behavior from one group as compared to the other. It is doubtful that such a pattern could be explained on the basis of intake differences.

Aside from the expected postoperative excretion increase in potassium we note a proportionately smaller postoperative increase in the inadequate calorie group. One might speculate that a negative caloric balance implies greater cell breakdown to meet obligatory energy demands, thereby releasing more endogenous potassium and thus less need from exogenous sources, hence proportionately greater urinary loss of administered potassium. Statistical evaluation and more accurate conclusions will be the subject of future publications on these data.

In order to achieve equilibrium consistently all possible protein as blood or amino acids must be given. In our opinion all fluid given should contain amino acids and high caloric support.

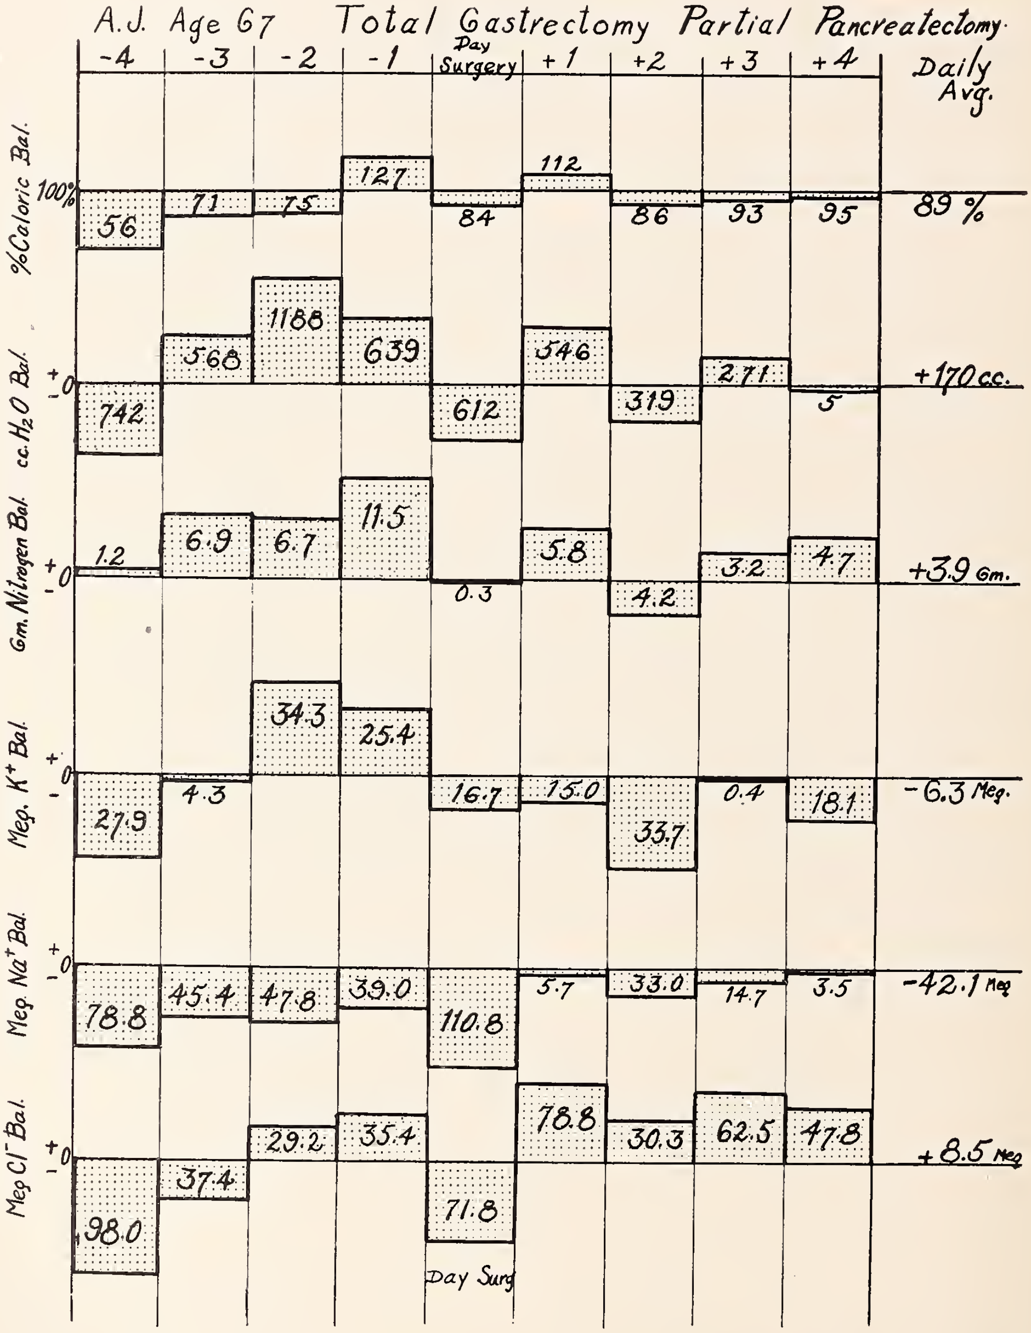

Fig. 4. Balance studies on a patient with gastric carcinoma (same as Fig. 3) reveal all balances close to equilibrium for nine days. The exception of sodium was intentional due to high initial sodium level.

Nitrogen Balance need not be calculated for the practical management of a case. Equilibrium or positive balance is of vital importance and is dependent upon adequate caloric and nitrogen intake.

Case Studies by Graphic Representation.—Figures 3 and 4 represent the blood chemistry studies and the balance calculations on a patient with carcinoma of the stomach. The moderately negative sodium balance was the result of planned therapy since the serum sodium was high at the outset. Hypernatremia is likely to be particularly bad in the face of a reversed albumin globulin ratio. Other factors were maintained very near equilibrium and the patient was discharged from the hospital the eighth postoperative day.

In burn cases, an accurate electrolyte and fluid balance is impractical. Therefore, the blood chemistries must be observed even more closely. Figure 5 and Table VI represent determinations on a fourteen-year-old girl with a 68 per cent body surface burn, 30 per cent of her body surfaces requiring grafting. On a high caloric intake and close electrolyte and fluid adjustment the patient was discharged at 106 days without dressings and returned to school two weeks later.

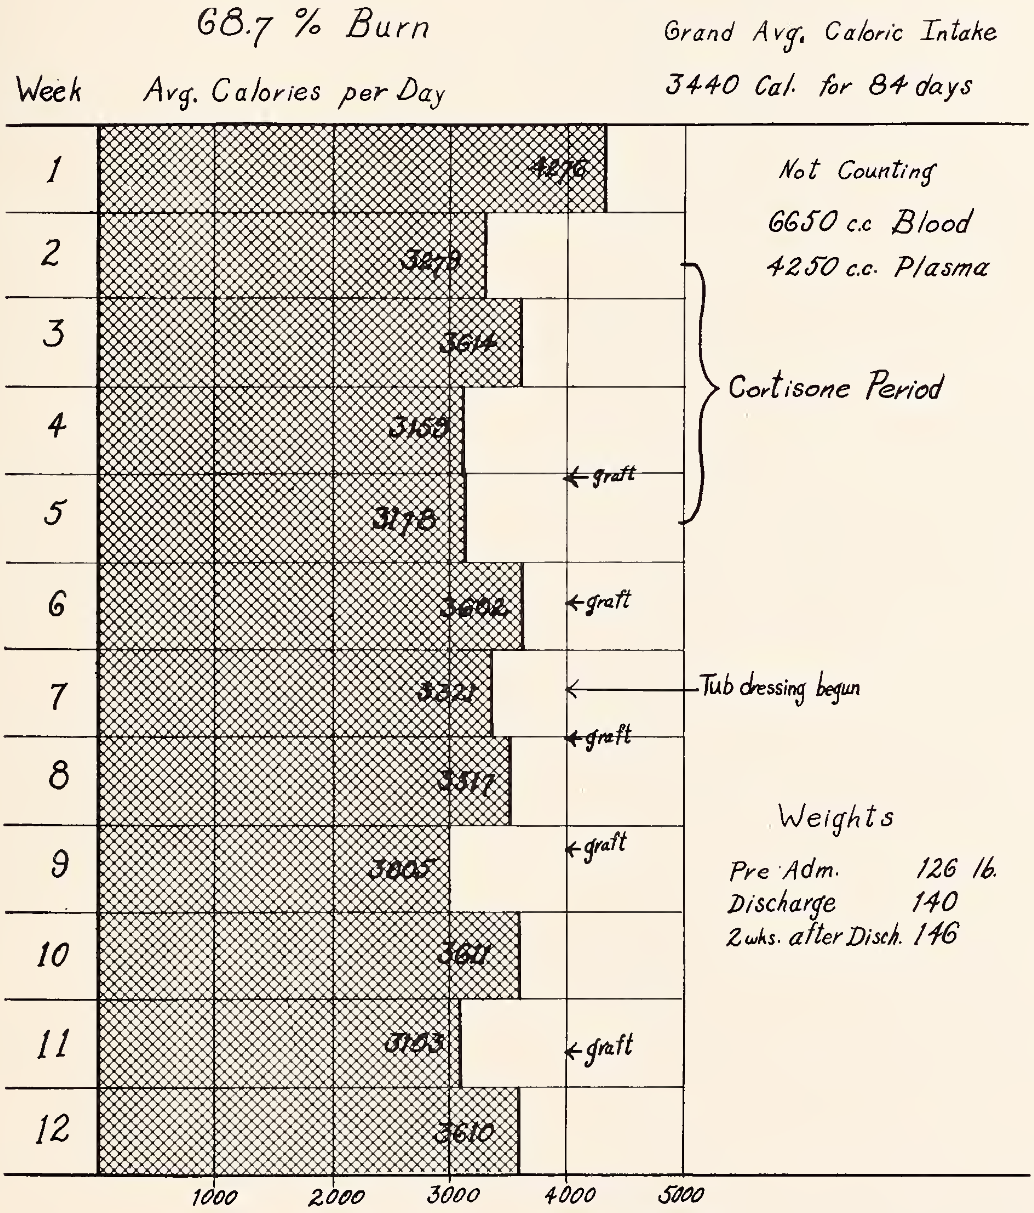

Fig. 5. An extensively burned patient can be maintained on high caloric intake by fluid infusions of 1000 calories per liter solution.

High caloric intake was attained by parenteral supplement (Fig. 5), particularly during the first week, of a solution containing 1000 calories per liter (6 per cent amino acids, 12 per cent invert sugar and 5 per cent alcohol). Cortisone therapy was tried for a three-week period as a further attempt to increase her appetite, but no change was found so it was discontinued. We attribute her survival and rapid healing to her youth, balanced

high caloric parenteral and oral feedings, and to careful attention to blood, fluid and electrolyte administration.

The blood chemistry profile is an invaluable guide to therapy (Table VI). Attention may be called to the rise of hemoglobin and hematocrit at the end of the first twenty-four hours. The blood sugar of 332 on the day after admission is no doubt a reflection of the carbohydrate disturbance secondary to stress. We now believe that insulin should be given at that time as an aid in prevention of electrolyte anomalies. The reversal of the A/G ratio persisted, in spite of high caloric intake, until after skin grafting had been completed. During this period repeated whole blood transfusions were needed to correct anemia.

General Rules and Miscellaneous Suggestions

1. Fluid volume management is best accomplished by accurate daily weights which are checked against output measurements and insensible water loss calculation.

2. Fluid and electrolyte balances should be maintained at equilibrium except in correction of a prior deficit (repletion) or when a previous excess is being depressed (depletion).

3. An average preoperative sodium requirement is 105 mEq (6.2 gm.) and 74 mEq (4.4 gm.) in the postoperative period.

4. Potassium requirement averages 45 mEq (3.4 gm.) preoperatively as compared to 67 mEq (5.0 gm.) postoperative.

5. The electrolyte output in pooled samples of urine, suction, etc., is a valuable tool in balanced management. Output values are particularly useful when correlated with serum levels and state of hydration since deficits are recognized prior to drop of serum levels and onset of symptoms.

6. Water should be restricted on the day of surgery to about 2500 cc. above suction losses since the renal response to trauma is one of diminished water output.

7. Blood sugar levels, in the non-diabetic surgical patient, are very valuable since hyperglycemia is commonly associated with electrolyte disturbances. Insulin therapy aids recovery. The so-called pseudo diabetes of trauma is a very common observation in surgical patients. One unit of regular insulin to each four grams of carbohydrate will substantially aid carbohydrate metabolism. Much larger doses are occasionally required.

8. In hypochloremia associated with hypoproteinemia and edema, salt must not be given since the total body chloride quantity is likely normal. The serum chlorides will rise as protein replacement dispels the edema.

9. Hypochloremic alkalosis usually is pathognomonic of potassium deficiency and sodium chloride administration only increases the alkalosis. Serum sodium and potassium are essential laboratory information.

10. In gastric alkalosis due to loss of hydrochloric acid, there has been a great loss of chloride ion without a proportionate loss of sodium. In such cases give 0.6 per cent to 2.0 per cent ammonium chloride, some chloride as potassium chloride, or 6 cc. of concentrated hydrochloric acid (60 — 72 mEq) in 1000 cc. of 5 per cent amino acid solution as a buffer.

11. Ammonium chloride should not be given in the presence of shock because the ammonia ion is very toxic. If the shock state liver does not rapidly convert ammonia to urea toxicity will rapidly appear.

12. Acidosis, with a normal or high chloride, is best managed with 1/6 molar lactate. Again a fairly normal liver function should exist to insure handling of the lactate radical.

13. Electrolyte replacement is best done by adding the desired mEq of each electrolyte from stock concentrates to each liter of basic fluid, thus avoiding the need to order a liter of this and a liter of that.

14. Finally, a high caloric, adequate protein intravenous fluid diet with the addition of the desired electrolytes affords a more smooth and balanced management of the patient's physiologic needs.

WANTED—A NEW LOOK AT MEDICAL MANPOWER PROBLEMS

Congressional re-evaluation of the physician draft, with more attention paid to the needs of medical education and research, is advocated by Dr. Dean F. Smiley, secretary of the Association of American Medical Colleges, in an editorial published in the March issue of the *Journal of Medical Education.*

Dr. Smiley warns that the nation's potential supply of medical teachers and researchers will be seriously depleted if the present policy of drafting young physicians is continued in its present form. Since the beginning of World War II, Selective Service has delivered as many doctors to the Armed Forces as they estimated they would need.

The vagaries of Selective Service requirements, he says, in some essential respects have been neither fixed nor fair. Interpretations of rulings which vary from state to state, changes in physical qualifications and other factors have tended to keep young physicians, educators and researchers in confusion.

Military service or the threat of it has made long-term planning almost impossible for these men. In addition, more than 3,000 graduate students in the sciences have had their careers interrupted or terminated by military service. "How long," asks Dr. Smiley, "can this nation continue to ignore the need for medical teachers and researchers before we find ourselves falling behind Russia in our ability both to train new physicians and to carry out important life-saving research in such fields as aerophysiology, antibiotic therapy and radiation therapy?"

Complete Obstruction of the Bowel in the Newborn

ROBERT W. GIBBS, M.D.
Minneapolis, Minnesota

BECAUSE many disturbances in the various systems of the newborn result in symptoms that are common to intestinal obstruction, it is often difficult to recognize specific types of obstruction. Yet if obstructions are not recognized early, the newborn may die. Even if the newborn lives long enough for the diagnosis to be made and corrective procedures to be carried out, every hour, even every minute increases the hazard to the newborn.

By limiting these obstructions to the ones obvious shortly after birth, the congenital anomalies become the most frequent source of obstruction. The incidence of various types of intestinal obstruction seen without any limit to age shows that the congenital anomalies are relatively unimportant (Fig. 1).

At St. Mary's Hospital in Minneapolis from 1942 through 1951 there were 24,594 live births. In this group there was a malrotation of the colon, an ileal stenosis with angulation of the bowel, an ileal atresia, a persistent cloaca with a persistent common membrane, and a meconium ileus. That is five congenital anomalies with complete bowel obstruction in 24,594 cases or close to one per 5,000 live births.

1. *Congenital atresia of the intestine and colon* occurs once in 20,000 births. Although the exact causes of atresia cannot be given, one can safely say they are developmental abnormalities accompanying faulty embryologic events. Ladd and Gross say that such events occur between the fifth and tenth week of fetal life, because before that time and after that time there is a rapid proliferation of epithelium from the pylorus to the ileocecal valve which obliterates the lumen. The formation of vacuoles and then the coalescence of these cystic spaces re-establishes the lumen. Arrest of growth at this period anywhere from the pyloric sphincter to the ileocecal valve may ensue in an atresia. The most frequent site of such an obstruction is in the lower ileum and jejunum. In 392 cases collected by Davis and Poynter, 161 were in the jejunum and ileum.

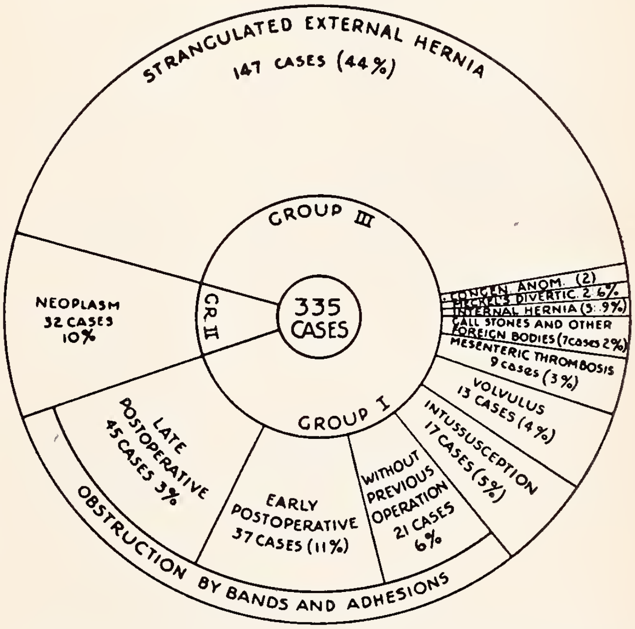

Fig. 1. The incidence of various types of intestinal obstruction, over a ten-year period at the Massachusetts General Hospital, during which time there were 39,936 surgical admissions, 335 cases of bowel obstruction were seen. The high incidence of strangulated hernia in this series is striking. (Reprinted by permission of Wangensteen, O. H., from "Intestinal Obstruction", ed. 2).[7]

Figure 2, taken from Ladd and Gross, shows the usual distribution of sites of obstruction. The obstruction is usually single but occurs in multiple areas in 15 per cent of the cases.

The obstruction may occur in two forms. There may be an internal diaphragm or veil which completely blocks the lumen, or there may be a blind sac of proximal intestine connected to the caudal section by a fibrous band. Above the obstruction, the bowel may be so distended as to rupture. Below the obstruction the bowel is collapsed and ribbon-like, especially in low obstructions.

When the obstruction occurs high in the intestinal tract the child usually has symptoms

---

Inaugural Thesis presented before the Minneapolis Academy of Medicine, November 17, 1953, Minneapolis, Minnesota.

early. They always occur within the first day of life. Vomiting which becomes more and more frequent and intense is a major symptom. There may or may not be bile in the vomitus, depending on the level of the obstruction. Obstructions above the papilla of Vater are rare, so that nearly all such infants have bile-stained emesis. The stools are usually scanty in amount and drier than normal. The color is usually not so tarry. The degree of abdominal distention depends upon the level of the atresia. A high obstruction may show little distention because the baby can keep the stomach empty by vomiting. An atresia in the jejunum will show marked and general distention due to gas in the bowel above the obstruction which is not expelled with vomiting. A low atresia often shows intestinal patterning. If fever is present, it is usually due to dehydration and/or peritonitis following rupture of the bowel.

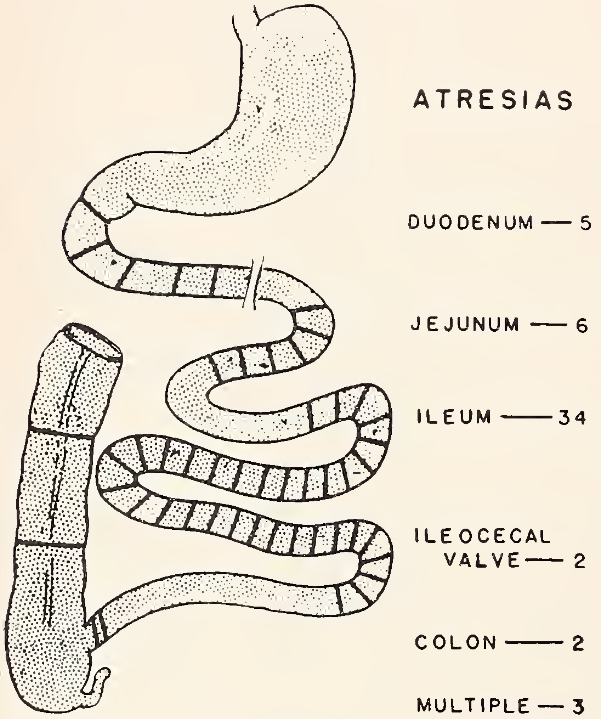

Fig. 2. Diagram showing position of atresias in fifty-two cases. (Reprinted by permission of Gross, Robert, from "Abdominal Surgery of Infancy and Childhood").[2]

Because of its aid in locating the point of obstruction, roentgen examination is important. Gas in the stomach and duodenum, without gas in the lower intestine, locates the obstruction in the duodenum. A thin mixture of barium or lipiodol orally will locate a high obstruction, and a barium enema will locate an obstruction in the colon. Actually, the use of contrast media is seldom needed, and to avoid the danger of aspiration, lipiodal is preferred.

Farber's test will help one determine if the obstruction is complete or partial, and also if it has been present since before birth. The meconium is examined and the presence of vernix cells (cornified epithelial cells) can quickly be established.

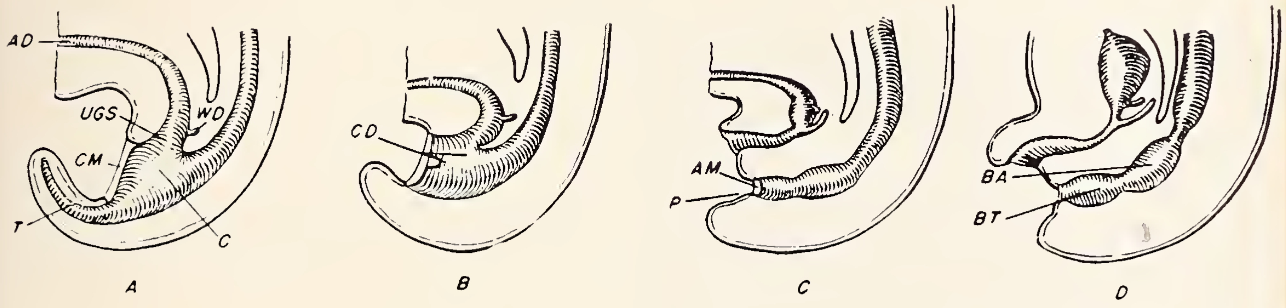
A low bowel obstruction can be differentiated from imperforate anus by external inspection and the passing of a bougie or a barium enema. A high bowel atresia can be differentiated from internal herniation of the bowel or volvulus by absence of bile in the meconium. Also, the abdomen is flaccid and non-tender in an atresia, in contrast to tenderness in internal herniation or volvulus.

2. *Malrotation of the intestine and colon* is much more complicated than atresia as to etiology. To try to visualize it quickly and yet clearly, picture the gut first as a long tube and then as a tube with a "U" shaped piece but still in a single plane suspended by a common dorsal mesentery. Now think what would happen when one section of this tube grows more rapidly than another. It would either have to extend a greater distance, which it can't do because of it's abdominal limitation, or twist to take up the slack. To add to the slack, the "U" shape which is the portion of the intestine protruding through the umbilical orifice now returns to the abdominal cavity. This is at the tenth week of fetal life. The position that various parts of the intestinal tract will take in relation to each other is the result of the intestine rotating in a counter-clockwise manner; and because the cecum is the last part to return to the abdomen, the colon is carried forward over the superior mesenteric artery.

The malrotation may be due to non-rotation of the midgut loop, reversed rotation of the midgut loop, or some other abnormal rotation of the midgut loop. In reversed rotation, the transverse colon lies behind the superior mesenteric artery, giving rise to constricting bands, and there is a lack of attachment of the mesentry along the posterior abdominal wall, predisposing to volvulus.

There are two main features of a malrotated bowel. One is obstruction near the duodeno-jejunal angle occasioned by abnormal adhesions, that is, bands lying directly across the descending portion of the duodenum and obstructing by extrinsic pressure. The other is a volvulus of the small bowel, cecum, and ascending colon or torsion about the superior mesenteric artery. The symptoms are vomiting, abdominal distention, peristolic waves, dehydration, and fever. X-ray will show a gas-filled stomach and duodenum. If there are no bands across the duodenum, there will be an enormously dilated jejunum and ileum. A barium enema will show the cecum in the right epigastrium in an incompletely rotated position. Laboratory findings are of little or no importance. The only change is a change consistent with dehydration. It may be difficult at times to differentiate this from intestinal atresia, but once it has been established that surgery is necessary, this point is not too important.

3. *An imperforate anus* occurs once in 5,000 newly born babies. In the embryo, there is a period when the urogenital and intestinal tracts open into a common cavity, the cloaca. This is closed from the exterior by a cloacal membrane. As the embryo develops there is a cleavage of the urogenital tract from the intestine. The two are entirely separate at the seventh week (Fig. 3). Late in the seventh week the urogenital membrane, the anterior part of the original cloacal membrane, opens; and later the anal membrane (the posterior part) opens. Arrest in development at this stage results in an imperforate anus or a stenosis. There are four types of anal anomalies (Fig. 4). These are:



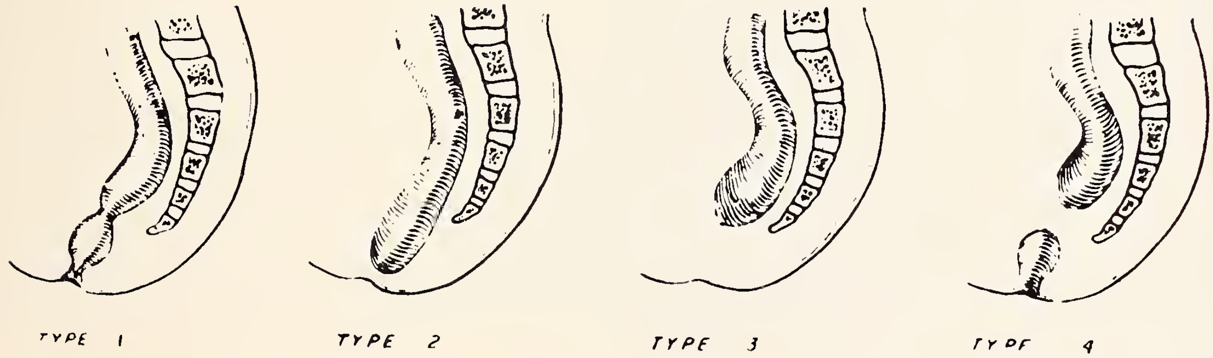


Fig. 3. *(Above)* Normal development of the anus and rectum. A, 7.5 mm. stage. B, 9 mm. stage. C, 22 mm. stage. D, 42 mm. stage.

Fig. 4. *(Below)* Types of anal and rectal abnormalities. Type 1—Stenosis at anus or at a point several centimeters above the anus. Type 2—Imperforate anus. Obstruction due to persistent membrane. Type 3.—Imperforate anus. Rectal pouch ending blindly some distance above anus. Type 4—Anus and anal pouch normal. Rectal pouch ends blindly in hollow of sacrum. (Reprinted by permission of Gross, Robert, from "Abdominal Surgery of Infancy and Childhood.")[2]

1. Stenosis of anus or just above anus,
2. Imperforate anus,
3. Imperforate anus with rectal pouch ending blindly, and
4. Anus normal with rectal pouch ending blindly.

The most difficult to diagnose is type four. The easiest types to treat are types one and two.

No type of bowel obstruction is more easily recognized than the first three types. Clinically a child will take feedings for at least twenty-four hours before regurgitation begins. The external recognition of the imperforate anus is apt to be discovered before any obstructive symptoms develop. The x-ray is a big help in determining the type of obstruction present. The Wangensteen-Rice maneuver is a help in locating the height of the blind pouch. An x-ray is taken of the infant in an upsidedown position. The height the gas ascends will determine the level of the blind pouch. One must not rely on this method before twenty-four hours have elapsed to allow time for the gas to pass through the sticky meconium. About twenty-eight per cent of these children have associated anomalies.

Fig. 6. *(Below)* Diagrammatic representation of mode of development of annular pancreas. Free end of ventral pancreatic anlage becomes fixed so that during its subsequent migration, with rotation of duodenum toward dorsal anlage it is drawn out. With fusion as shown at right, it comes to surround duodenum (after Lecco). (Reprinted by permission of May, Charles D., editor of *Pediatrics*)[5]

4. Extrinsic bands, aside from those associated with malrotation of the gut and post-surgical complications, are rare. However, one special type will be discussed, the annular pancreas. This obstruction is due to a complete encirclement of the duodenum by a ring of pancreatic tissue. The majority of individuals with an annular pancreas do not develop symptoms until they have reached adult life, or they may never develop symptoms and the finding is one at the autopsy.

Normally, the pancreas develops as two distinct entodermal diverticuli known as the dorsal and ventral anlage. The dorsal anlage becomes the body and tail of the pancreas. The ventral anlage comes off the primitive bile duct and forms the head of the pancreas. At six weeks in fetal life the two portions fuse. This is the period when the anomaly arises (Fig. 5). To cause obstruction, one of three situations arises. First, if the ventral anlage does not rotate to its normal posterior position there will be pancreatic tissue on both sides of the duodenum. Second, if the ventral anlage becomes adherent to the duodenum, the rotating of the duodenum merely stretches the ventral anlage to form a ring. Third, an unusual overgrowth of one of the ducts may lead to complete encirclement of the duodenum (Fig. 6).

In this condition there is vomiting, upper abdominal distention and visible persistaltic waves, decreased size and frequency of meconium stools, progressive weight loss, and dehydration. On x-ray there is a dilated stomach and dilated proximal duodenum. Barium studies are not necessary.

5. Another congenital anomaly is *agenesis of the myenteric plexus.* These children have vomiting, constipation and abdominal distention during the first four days of life. The picture is more like a lower bowel obstruction. The x-ray will show fluid levels if taken in the upright position. A barium enema will help locate the gas and will show *normal* and dilated bowel. Although the junction between normal and dilated bowel is usually the point of change from abnormal to normal innervation, one cannot accept the roentgenographic findings or the operative findings as evidence of this junction. There may be a considerable segment of dilated bowel that contains no ganglia. The normal or spastic appearing bowel is the area of abnormality (Fig. 7).

6. In an infant with *meconium ileus* the entire intestine is full of tough and inspissated meconium. The end result is obstruction and fairly often a perforation of the intestinal wall. On autopsy, obstruction of the bile duct, the pancreatic duct or both is a finding. Any child that has this probably has cystic fibrosis of the pancreas. The symptoms are the same as in high obstruction—vomiting, abdominal distention and absence of stools.

Case 1.—B.G.H. was a girl born August 21, 1950. She weighed 2.67 kilograms and had a normal delivery. Her postnatal examination on August 22, 1950, was essentially normal, no vomiting or abdominal distention. Vomiting started August 23, two days after delivery. Atropine sulfate was ordered to be given before feedings and subcutaneous fluids were ordered. The child had a meconium stool on August 23, 24 and 25. No more stools were recorded to the date of surgery, August 31.

Fluoroscopic examination on August 28 (seven days after birth) showed a barium swallow progress to the mid-duodenum. The impression was partial obstruction on the basis of a volvulus. Some of the barium passed through. A barium study of the colon showed incomplete rotation of the colon with the major portion of the colon in the left side of the abdomen. An operation, done August 31, revealed the cecum and ascending colon in the left upper quadrant, wrapped around the root of a midgut volvulus in a 360 degree turn.

There were transduodenal bands extrinsic in location across the third and fourth portions of the duodenum. There were a few additional bands over the proximal jejumen. After untwisting the bowels and cutting the bands, the wound was closed. The child is now two years and two months old and doing well.

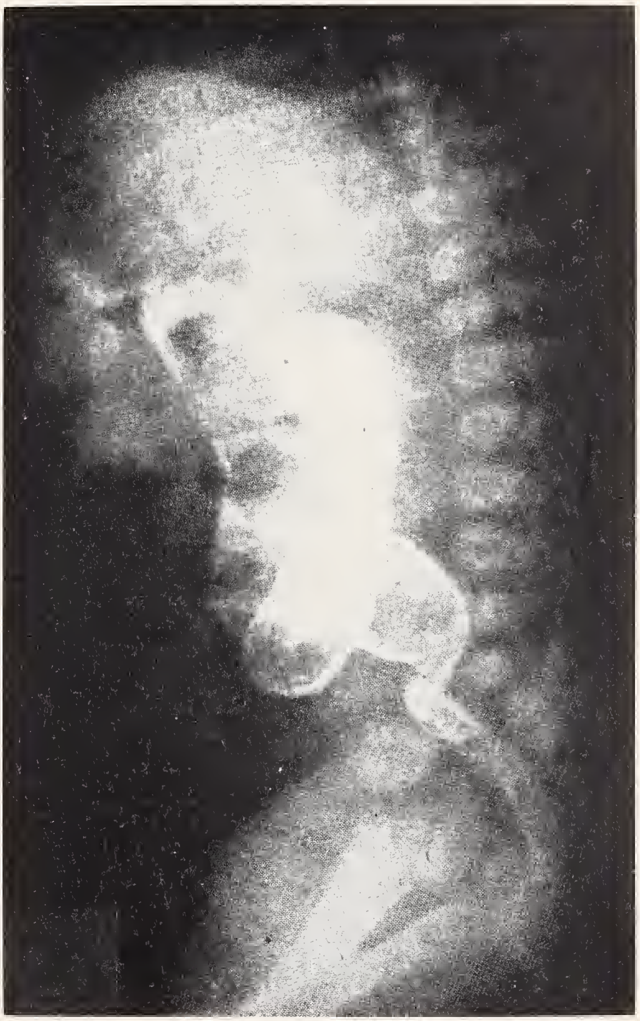

Fig. 7. Small barium enema illustrates narrow spastic rectum and rectosigmoid with dilated bowel above. (Reprinted by permission of May, Charles D., editor of *Pediatrics.*)[5]

Case 2—B.G.T. was a girl born October 15, 1950. The child was cyanotic at birth but pinked up rapidly with oxygen. She weighed 2.14 kilograms. One thing that was misleading to the doctor who saw the case originally is that the child did not vomit apparently large amounts, although the weight loss was 373 grams in four days. The explanation of the peculiar type of vomiting was discovered when the baby was lavaged and 300 cc. of fluid was removed from the stomach. On October 20, 1950, the baby was dehydrated, jaundiced, lethargic and had a distended abdomen. The x-ray showed a marked distention of the stomach with fluid and gas compatible with a high grade obstruction in the region of the pylorus. An operation done the same day, October 20,

ACH

ACHROMYCIN has proved effective against:

- Pharyngitis
- Acute Bronchitis
- Tonsillitis
- Pertussis
- Otitis Media
- Scarlet Fever
- Osteomyelitis
- Epidermal Abscesses
- Acute Brucellosis
- Pancreatic Fibrosis
- Typhus Fever
- Sinusitis
- Gonorrhea
- Bacillary Dysentery
- Pneumonia with or without Bacteremia
- Bronchopulmonary Infection
- Acute Pyelonephritis
- Chronic Pyelonephritis
- Mixed Bacterial Infections
- Soft Tissue Infections
- Staphylococcal Septicemia
- Pneumonoccal Septicemia
- Urogenital Tract Infections
- Acute Extraintestinal Amebic Infections
- Intestinal Amebic Infections
- Subacute Bacterial Endocarditis

ROMYCIN*

HYDROCHLORIDE
Tetracycline HCl *Lederle*

A TRULY BROAD-SPECTRUM ANTIBIOTIC

Clinical research has proved ACHROMYCIN to be effective against more than a score of different infections, including those caused by Gram-positive and Gram-negative bacteria, rickettsia, certain viruses and protozoa.

In addition to its true broad-spectrum activity, ACHROMYCIN provides more rapid diffusion than certain other antibiotics, prompt control of infection, and the distinct advantage of being well tolerated by most persons, young and old alike.

ACHROMYCIN, in its many forms, was accepted by the medical profession in an amazingly short time. Each day more and more prescriptions for ACHROMYCIN are being written when a broad-spectrum antibiotic is indicated.

Blood Volume Studies In Gastrointestinal Hemorrhage

BERTON D. MITCHELL, M.D.
Minneapolis, Minnesota

EVEN THOUGH standardization of diagnostic procedures and therapy is a goal sought after by most of us in the medical profession, it should not be assumed by any of us that similar lesions should be handled in the same manner by all surgeons anymore than we should assume that all surgeons have equal facilities and skill. This fallacy seems to be especially prevalent in the discussions of the management of gastrointestinal bleeding. The procedure of choice in each case, whether in diagnosis or treatment, is that which yields the best results in that surgeon's hands. An attempt will be made here to bring out a point which should better assist one in evaluating the condition of a gastrointestinal bleeder.

We have all seen patients with gastrointestinal bleeding who we know have bled as much as one-third or one-half of their total blood volume and still do not exhibit the classical signs of shock as we know it. On the other hand, why are some patients with considerably less bleeding in profound shock when we see them. The answer, in most cases, appears to be in the total blood volume and red cell mass studies before the bleeding starts and after we see that patient.

TABLE I. NORMAL VALUES FOR A 70 KG. MALE WITH A HEMOGLOBIN OF 16 GM AND A HEMATOCRIT OF 46 PER CENT.

Blood Volume	Weight in Kg. x 85	6000 *cc*
Plasma Volume	Weight in Kg. x 45	3200 *cc*
Red Cell Mass	Weight in Kg. x 40	2800 *cc*
Total Hemoglobin	16x $\frac{6000}{100}$	960 Gms.

46% of 6000—2800 *cc* red cell mass
6000—2800 *cc*——3200 *cc*——plasma volume

TABLE II. VALUES FOR A 70 KG. MALE WHO HAS HAD A SUDDEN LOSS OF ONE-THIRD OF HIS BLOOD VOLUME BY HEMORRHAGE.

Blood Volume	4000 *cc*
Plasma Volume	2133 *cc*
Red Cell Volume	1867 *cc*

Hemoglobin—16 Gms/100 *cc*—640 Gms total.
Hematocrit—46%.

TABLE III. VALUES AFTER EXCHANGE OF FLUID BETWEEN VASCULAR BED AND INTERSTITIAL SPACES.

Blood Volume	5000 *cc*
Plasma Volume	3133 *cc*
Red Cell Volume	1867 *cc*
Total Hemoglobin	640 Gms.

Hemoglobin per 100 *cc*=12.8 Gms.
Hematocrit—37.3%.

Table I shows the normal values for blood volume, red cell mass and plasma volume in a 70 Kg. male with a hematocrit of 46 per cent and a hemoglobin of 16 gm. If this man should suddenly lose one-third of his blood volume by hemorrhage, he would then have remaining the values shown in Table II. This total of 4000 cc. blood volume is only theoretical because we know that along with the vascular constriction that takes place, there is also an exchange of fluid from the interstitial spaces into the vascular bed so that we would have a volume of, say, 5000 cc. The number of red cells is decreased by one-third so that the hemoglobin and hematocrit are lowered.

Table III shows how this affects the plasma volume, hemoglobin and hematocrit. This hemoglobin of 12.8 gm. and hematocrit of 37.3 per cent are not far off the normal and may not cause us much alarm, especially if we think the bleeding has stopped. However, most of the patients with gastrointestinal hemorrhage are still bleeding when we see them and may continue to bleed for some time during our care. Also we know that a good percentage of these patients will bleed again, and each time they bleed there is a further loss of total hemoglobin from the circulating blood.

In a similar manner the circulating proteins will be reduced from a normal figure of 6.0 gm. per 100 cc. blood to a corresponding low after the volume is reduced and then diluted as it increases. Table IV shows the effect on total plasma proteins.

From these figures on a hypothetical case, it can be readily seen that further hemorrhage at this

---

Read before the Minneapolis Academy of Medicine, March 16, 1954.

TABLE IV. PROTEIN VALUES BEFORE AND AFTER THE HEMORRHAGE.

Total Proteins ....6.0 Gms./100 *cc*

or $\frac{\text{Plasma Volume}}{100} = \frac{3200 \times 6}{100} = 198$ Gms. total protein.

After the bleeding

$\frac{2133}{100} \times 6 = 128$ Gms. total protein.

After increase of plasma volume to 3133 *cc* the total protein is still 128 Gms. or 4.1 Gms./100 *cc*.

time or even after inadequate transfusions of whole blood will seriously jeopardize this patient's life. This is especially true if surgery is contemplated on this patient because with the added trauma of surgery, anesthesia and surgical hemorrhage, the seriousness of this situation could become alarming.

Of equal importance in the therapy of hemorrhage is the condition of that patient with respect to blood volume and red cell mass before he starts bleeding. These patients may have depleted values in blood volume as a result of nutritional disturbances, heart disease, chronic infection, slow chronic bleeding or malignancy. For purposes of simplification it might be said that this type of patient is suffering from "chronic shock."

This chronic shock has been defined as a syndrome characterized by weight loss, diminished blood volume, increased interstitial fluid volume and an increased susceptibility to shock from anesthesia, surgical trauma, or a physiological shock condition such as hemorrhage.

It is readily apparent from the above example of change in blood volume, red cell mass and plasma proteins that profuse bleeding is much more likely to cause the patient to fall into a shock-like state than a normal healthy individual.

The total protein will be especially affected because during this subpar state the patient is continually using his supply of stored protein and in any emergency he would not have this supply to fall back upon in order to maintain an adequate plasma protein value.

From this, it is quite obvious that the patient with rapid bleeding will show close to normal hemoglobin, hematocrit and plasma protein values. However, in the patient with the same amount of bleeding over a longer period of time, these values are lower than normal. In this type of patient, the plasma volume will be near normal and on receiving transfusions, this plasma volume changes very little. The mechanism of this phenomenon is that there is an exchange of fluid between the circulating blood and the extracellular spaces. In this case the goal should be replacement of the red cell mass and not the blood volume.

The test most used at this time for the determination of the plasma volume is the Evans blue dye method. This involves the intravenous injection of the dye. After ten minutes a specimen of blood is obtained from the opposite side of the body. No tourniquet is used. The plasma from the centrifuged blood is then compared by a colorimetric method with a photo-electric spectrophotometer. This method has been shown to be accurate to within 3 per cent. Another test which has been used more recently is the use of tagged radioactive ions. This is thought to be more accurate than the Evans blue dye method but for all practical purposes the dye method is probably accurate enough.

In conclusion, I would like to leave the following facts to be noted whenever one is confronted with a patient on whom surgery is contemplated and who has experienced hemorrhage either slow or fast or, for other reasons mentioned, presumably the plasma volume or red cell mass is altered.

1. The hemoglobin and hematocrit levels and other clinical signs or lack of signs of shock are not accurate guides to severity of hemorrhage.

2. The red cell mass is a more important determination to know than the hemoglobin and hematocrit in order that a true evaluation of the patient's condition may be known.

3. Because there are shifts in fluids between the plasma and the interstitial space and also at the same time shifts between the interstitial space and the intercellular space, it would be better to defer surgery in many cases until adjustment has been reached.

4. Because the shift of these fluids is not a rapid process but is not complete for at least twenty-four hours, it is probably better to defer surgery until the patient has had time to adapt to his increased blood volume and to his electrolyte fluid balance. Also because of this, transfusion should not be pushed too rapidly unless the patient is in clinical shock. There is always the danger of overloading the circulation and throwing the patient into cardiac failure with pulmonary edema and the subsequent complications.

Gynecological Cancer Detection

Findings at University of Minnesota Cancer Detection Center

MELVIN B. SINYKIN, M.D.
and
MAXWELL M. BARR, M.D.
Minneapolis, Minnesota

IN THE PAST two decades increasing emphasis has been placed on the early detection of carcinoma. The importance of periodic examinations and the recognition of early symptoms have been the basis of educational programs directed at the medical profession as well as the lay public. As a by-product of these efforts, over 133 cancer detection centers have been established in this country since 1937.[1,8] The Cancer Detection Center at the University of Minnesota was established in March, 1948, with the approval of the Minnesota State Medical Association. Examinations have been limited to men and women over the age of forty-five years. The scope of the examinations and the results obtained have been reported elsewhere.[5,7,10]

This report deals with the results of gynecological examinations and special diagnostic procedures performed upon 3,087 women from March, 1948 to October 6, 1953. During this period the following routine has been used for the systematic examination of the female pelvis: (1) A brief history is obtained to elicit the presence of abnormal bleeding or discharge. (2) The lower abdomen is inspected and palpated. (3) The external genitalia are inspected and palpated. (4) Vaginal secretion is aspirated for the vaginal smear. (5) Speculum examination of the vagina and cervix is performed and a cervical smear is taken with an Ayres' wooden spatula. Since 1950 an additional routine has included the insertion of a small piece of gelfoam into the endocervix. If bleeding results the gelfoam is placed in formalin and sent to the pathology laboratory for preparation of sections similar to tissue biopsy. The slide is examined by the pathologist for the presence of abnormal cells in the interstices of the gelfoam as described by Gladstone.[3] (6) Bimanual examination and recto-vaginal examinations are performed.

In addition to the above routine, the following procedures are performed when indicated: (1) Punch biopsy of the cervix is taken when an abnormal lesion or bleeding area is found. When the Papanicolaou studies are reported positive or suspicious, repeated smears are made. If these are positive, biopsies are taken from target areas indicated by Schiller's Gram iodine test. If target areas are not found, biopsies are taken in the four quadrants of the cervix, or a cone of cervical tissue is removed with a Gusberg cone biopsy instrument. (2)) Small cervical polyps are avulsed with Bozeman uterine dressing forceps or the Pratt forceps. When a history of abnormal bleeding is obtained, the patient is referred back to her own physician for dilatation and curettage. (3) When cervical smears are positive but biopsies of the cervix fail to reveal carcinoma, the patient is referred to her physician for dilatation and curettage and either repeat biopsies or knife conization of the cervix. (4) When other lesions or pelvic masses are found, the patient is referred to her physician for further observation or therapy as indicated. (5) Endometrial aspiration smears have more recently been made on patients with abnormal uterine bleeding or discharge in an attempt to improve the screening of patients with endometrial carcinoma. Figure 1 illustrates some of the instruments used for routine and special procedures during the gynecological examination.

The vaginal and cervical smears are stained and

Presented before the Minneapolis Academy of Medicine, April 20, 1953.

This material includes examinations through October 6, 1953, or five and one-half years of operation of the center. The authors wish to acknowledge with thanks the co-operation of Dr. Claude R. Hitchcock, director of the center, in making the records and facilities available for this study. Mrs. Lydia Linsey has been most helpful in assembling data necessary for this report.

The authors have attended the center as gynecological examiners since its inception. The Cancer Detection Center is sponsored by a grant from the Minnesota Division of the American Cancer Society.

examined by the technicians in the laboratory of the Cancer Detection Center. Suspicious smears are examined by the pathologist in the University Hospitals for final classification. Technician screening has resulted in a considerable saving of valuable time on the part of professional personnel.

Cancer of the Cervix

Table I shows the number of special examinations performed in the group of 3,087 patients examined from March 1, 1948, to October 6, 1953. The average number of examinations per patient was 2.2 during this five and one-half year period. One hundred and ninety-three cervical polyps were removed, and malignant degeneration was present in two.

Punch biopsies of the cervix were positive for carcinoma in six women. A total of eight carcinomas of the cervix have been detected among women who have attended the center (.26 per cent).

The experience with Papanicolaou smears is shown in Table II. The smears have been classified as follows: Class 1, normal appearing epithelium; Class 2, excessive number of pus cells; Class 3, atypical epithelial cells which are not frankly anaplastic in appearance; Class 4, frankly anaplastic appearing cells.

The relatively high percentage of false positive smears should decrease with increasing experience in reading the smears. Graham and Meigs[4] have shown that their group was able to reduce the percentage of false positive smears from 6.4 per cent to .04 per cent in a period of five years.

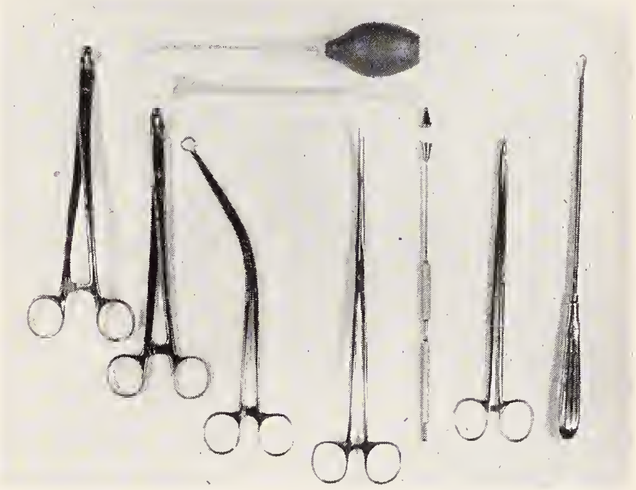

Fig. 1. Instruments used for detection of carcinoma of the internal female genitalia. Left to right are Thoms modification of the Gaylor biopsy punch, Gaylor biopsy punch, single tooth tenaculum, uterine dressing forceps holding gelfoam, Gusberg cone biopsy, Pratt forceps, and a small sharp curette. Above are a glass canula for aspirating vaginal secretion and the Ayres wooden cervical spatula.

The appearance of the cervix in the group of eight women with carcinoma of the cervix is described in Table III.

These findings indicate the lack of any characteristic gross appearance that will definitely identify early carcinoma of the cervix. Two patients with normal appearance of the cervix were detected with Papanicolaou smears graded Class 4. The smear diagnosis was confirmed by biopsy in each case.

Case 1.—M.C.O., aged sixty-two, para 3. At her third visit to the center her vaginal smear was found to be Class 4. Previous smears were Class 1. The cervix appeared normal. The vaginal smear (Fig. 2) revealed a typical anaplastic appearance. A biopsy obtained by her physician revealed early squamous cell carcinoma with no evidence of invasion.

Case 2.—P.F., aged fifty-four, para 2. At her first visit to the center her cervix appeared normal but the vaginal smear was Class 3. Repeat smears over a three-month period revealed Class 3 and later Class 4 smears. Schiller's test was positive around the circumference of

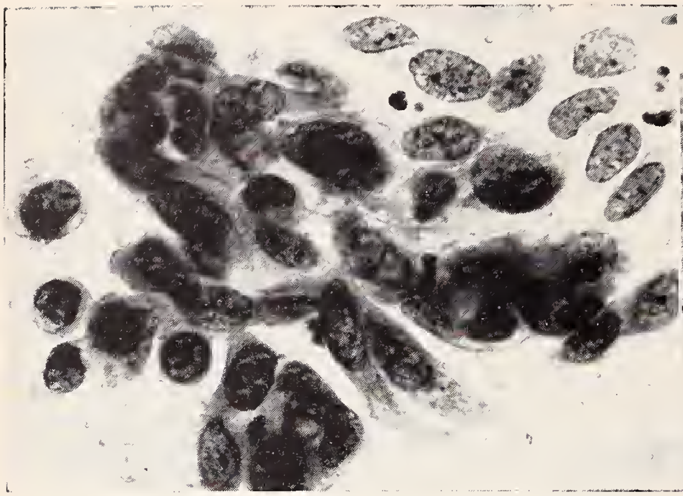

Fig. 2. Vaginal smear obtained from Case 1. Normal appearing cervix. Smear is Class 4. Biopsy taken elsewhere revealed squamous cell carcinoma.

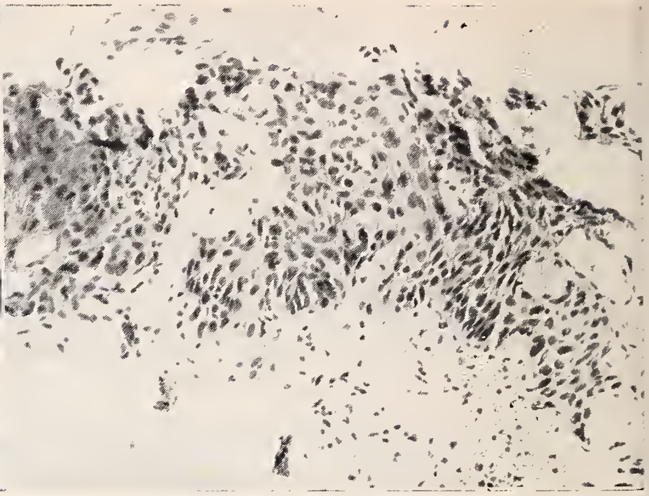

Fig. 3. Biopsy of cervix from Case 2. Normal appearing cervix. Positive Schiller's test after Class 4 smears. Gusberg cone biopsy reveals invasive squamous cell carcinoma.

the vaginal cervical junction. A biopsy was obtained with the Gusberg cone punch and was reported as showing invasive carcinoma of the cervix (Fig. 3).

The remaining six cases of carcinoma of the cervix were diagnosed by biopsy of abnormal lesions of the cervix. However, the routine Papanicolaou studies revealed Class 4 smears in three patients, a Class 3 smear in one patient, and normal smears in one patient. Figure 4 shows a Class 4 cervical smear obtained from a fifty-three-year-old woman, para 2. Biopsy of a small localized granular erosion of the cervix revealed early squamous carcinoma (Fig. 5). In six of the eight patients with positive cervical biopsies no evidence of invasion was found in the tissue examined. The following case is of interest because it was detected only by a set of fortunate circumstances:

Case 3.—E.A., aged forty-five, para 3. At her second visit to the center a biopsy was taken of a small area of the cervico-vaginal junction that bled easily. The tissue was examined by two pathologists, both of whom diagnosed chronic cervicitis. One report noted the presence of a few suspicious looking cells at the margin of the tissue section. Repeat biopsy was requested and was done two weeks later, several small bites being taken from the site of the previous biopsy. This area was located easily because the first biopsy site had been sketched by the examiner. The diagnosis now was definitely squamous cell carcinoma of the cervix (Fig. 6).

The gelfoam biopsy was saved and examined in five of the eight women found to have carcinoma of the cervix. These were interpreted as positive for carcinoma in one patient (Fig. 7), suspicious in three patients, and negative in one. The gelfoam test was not responsble for detecting carcinoma of the cervix but was found confirmatory in four of the five patients in whom the test was used.

Carcinoma of the Endometrium

Two women were found to have carcinoma of the corpus uteri during the first five and one-half years of the detection center's operation. Both presented the history of postmenopausal bleeding and both were referred to their own physicians for diagnostic curettage, which revealed the lesions. In both patients the pelvic findings were normal to bimanual examination and the surgical specimens revealed well localized lesions. Vaginal and cervical Papanicolaou smears were negative in both cases. This experience is similar to that at other centers and has led to the use of endometrial smears as a screening method.[9] Our experience with the endometrial smear is too recent for evaluation.

Carcinoma of the Ovary

Adnexal masses were palpated in 100 women. Of these, forty-five patients are known to have had pelvic laparotomy. Five patients were found to have carcinoma of the ovary. Four of these women were asymptomatic, and one complained of pelvic pain. Cystadenocarcinoma was found in four women, and one had primary adenocarcinoma. On September 1, 1954, four women were alive at four and one-half, three and one-half, three, and two years after surgery, and one patient had expired. Although cure is the excep-

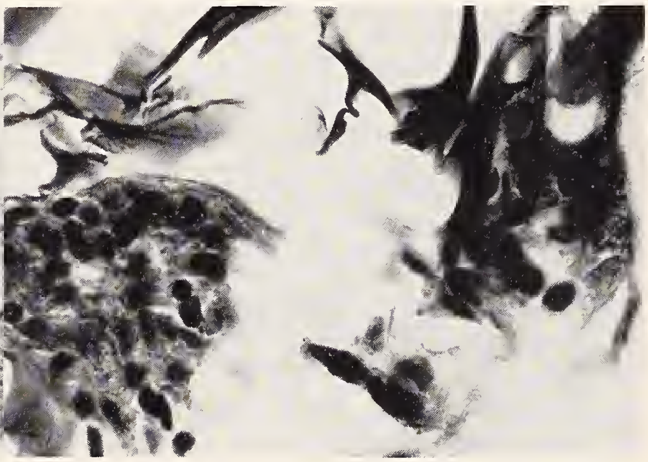

Fig. 7. Gelfoam biopsy of cervix from patient with small cystic nodule of cervix found to contain invasive squamous cell carcinoma.

tion, the early detection of carcinoma of the ovary offers an opportunity for adequate surgical therapy and prolongation of life.

Precancerous Lesions of the Female Pelvis

Probably the only disease process in the female pelvis that is associated with carcinoma in a significant percentage of women is leucoplakic vulvitis. This condition, as its name implies, presents a characteristic white thickening of the vulvar skin which is often confused with an exaggerated aging process of the vulvar skin known as kraurosis vulvae or, literally, shrinkage of the vulva. Kraurosis carries no increased threat of carcinoma while leukoplakia must be observed for the development of ulcers, fissures and induration of the involved skin. Biopsy will reveal the onset of carcinoma of the vulva. Patients with leukoplakic vulvitis have been referred to their physicians with the recommendation that they be examined every six months and biopsies taken as indicated. No carcinoma of the vulva has been detected at the center to date.

Myomata of the uterus may become sarcomatous in a small but definite percentage of women. The incidence of sarcomatous degeneration has usually been reported between 0.5 per cent and 1.0 per cent of all women with myomata.[11] In the general population this figure may be as low as 0.2 per cent. Sudden growth of these tumors, especially after the menopause, should indicate the danger of this complication.

Chronic cervicitis, leucoplakia of the cervix, cervical polyps and urethral caruncles are not

precancerous but may mask or be simulated by the appearance of early carcinoma. Figures available for the first four years of operation of the center reveal that 381 women (17.5 per cent) of the female population attending the center have had hysterectomies. The cervical stump was left in 275 women or 12.7 per cent of the total. Neither carcinoma in the cervical stump nor sarcomatous degeneration of a myoma has been found in any detection center patient.

Extrapelvic Cancer

Carcinoma was detected outside of the pelvis in forty-five women during the five and one-half years of this study. The location and number of these malignant tumors or conditions are indicated in Table IV.

Discussion

During the first five and one-half years of operation of the University of Minnesota Cancer Detection Center, 3,087 women over the age of forty-five years received 6,840 examinations. Eight women were found to have carcinoma of the cervix, two had carcinoma of the endometrium, and five had carcinoma of the ovary. Extrapelvic carcinoma was found in 43 women.

Biopsy of abnormal appearing areas of the cervix was responsible for detecting six of the eight carcinomas of the cervix. Cytological smear study was responsible for detecting two carcinomas of the cervix. Although the Papanicolaou studies have proved to be an important means of screening for carcinoma of the cervix, the current shortage of technicians capable of screening smears makes general usage of this method impracticable except in large centers of population. The gelfoam method of cytological study has not been responsible for detecting carcinoma but has indicated the need for further study in four of five cases. Carcinoma of the endometrium has been detected only by eliciting the history of abnormal bleeding and histologically proving the lesion after dilatation and curettage. Endometrial aspiration smears give promise of effective screening of carcinoma of the endometrium.

The follow-up of women who have attended the Cancer Detection Center is accomplished by contacting all examinees once each year in regard to returning for check-up. In this manner close contact is maintained with greater than 90 per cent of the center population. Up to the time of this report no examinee who was found to be normal on gynecological examination has been found on follow-up to have developed pelvic malignancy, with the possible exception of one patient who was subsequently found to have generalized lymphosarcoma of the abdominal viscera at laparotomy.

The accuracy of the screening pelvic examination to date would indicate that careful periodic examination and biopsy of all suspicious lesions will detect carcinoma of the vulva, vagina, cervix and ovaries in a high percentage of affected women. The Cancer Detection Center is valuable for testing and teaching new methods but cannot substitute for the doctor's office in reaching the bulk of the population.

Conclusions

1. Carcinoma of the cervix can be detected early by careful periodic examination and biopsy of all suspicious lesions. Vaginal and cervical smears are an important adjunct for early detection. Gelfoam biopsies have not proved valuable in this study.

2. Carcinoma of the endometrium can be detected early if women are educated to see their physicians for abnormal bleeding and the physicians follow through with adequate differential curettage. Endometrial aspiration smears offer better promise of effectively screening carcinoma of the endomerium than do vaginal and cervical smears.

3. Carcinoma of the ovary can be detected early only by periodic pelvic examinations and exploratory laparotomy for all newly developed and enlarging adnexal masses.

4. Carcinoma of the vulva is rare but will be detected early by biopsy of all suspicious lesions of the vulva particularly when the lesions are associated with leukoplakic vulvitis.

5. Significant reduction in mortality rates will

Ectopic Pregnancy

Diagnostic Analysis of Seventy Cases

MILTON E. BAKER, M.D.
Minneapolis, Minnesota

DURING the thirteen and one-half years from January, 1941, to July, 1954, there were seventy patients admitted to the Minneapolis General Hospital with the established diagnosis of ectopic pregnancy. In 1942 Dr. William P. Sadler presented an analysis of the 102 cases of ectopic pregnancy admitted to Minneapolis General Hospital during the nine-year period, 1932 to 1940. The current study analyzes the seventy cases from the standpoint of admission status, symptoms, and preoperative laboratory and physical findings; however, a more complete study, comparable to that of Dr. Sadler, is in the process of formulation.

TABLE I. SEVENTY ECTOPIC PREGNANCIES. MINNEAPOLIS GENERAL HOSPITAL, JANUARY 1, 1941, THROUGH JULY 1, 1954

Age		Para		Race		Marital Status		Amenorrhea	
Under 20	5 patients	0	14	White	58	Married	50	None	2
20-25	12	1	21	Colored	10	Divorced	11	4 weeks	3
25-30	26	2	12	Indian	2	Single	6	5-8 weeks	27
30-35	17	3	10			Widowed	3	8-12 weeks	27
35-40	8	4	6					12 or more	9
40 and over	2	5	5					Unknown	2
		6	0						
		7	1						
		Unknown	1						

The ages of these patients varied from seventeen to forty-two. Table I shows that the greatest number were in the 25- to 30-year age-group (twenty-six patients) with seventeen patients in the 30- to 35-year age-group. The racial distribution was: fifty-eight white patients, ten negroes and two Indians. Marital status was as follows: fifty married, eleven divorced, six single and three widowed. The parity, when known, varied from 0 to 7, with the largest number in the para 1 classification (twenty-one cases), and approximately equal distribution in the groups para 0, 2, and 3.

The record of amenorrhea was quite typical of ectopic pregnancy, with two patients reporting no amenorrhea, three with amenorrhea lasting four weeks, twenty-seven lasting five to eight weeks, twenty-seven lasting eight to twelve weeks, nine lasting twelve or more weeks, and two unknown.

The histories relative to vaginal bleeding prior to admission are shown in Table II. There was no bleeding in twelve cases, only one episode of bleeding in two cases, abnormal menses only in six cases, spotting only in seventeen cases, intermittent moderate bleeding in nine cases, continuous moderate bleeding in eighteen cases, profuse bleeding in seven cases, small clots passed in four cases, large clots passed in five cases, apparent tissue passed in six cases, and no history in one case.

TABLE II. VAGINAL BLEEDING AND PAIN PRIOR TO SURGERY

Bleeding		Pain	
None	12	None	1
One episode only	2	Shoulder pain	24
Abnormal menses only	6	Dull pelvic ache only	5
Spotting only	17	Abdominal cramping	18
Intermittent	9	Sharp pain with fainting	18
Continuous moderate	18	Sharp pain without fainting	41
Profuse	7	Rectal pain and or pain on defecation	17
Small clots	4	Dysuria	6
Large clots	5	Epigastric pain	5
Apparent tissue passed	6	Nausea and or vomiting	43
No history	1	No history	1

Type of pain experienced was also widely variable. The largest group, forty-one, reported sharp abdominal pain without syncope, and a substantial group, eighteen, reported sharp pain with syncope. Abdominal cramping alone or associated with

---

Presented before the Minneapolis Academy of Medicine, October 18, 1954.

other pain was reported by eighteen patients. Shoulder pain, in one or both shoulders, and always associated with some other type of pain, was reported by twenty-four patients. Nausea and/or vomiting, associated with pain or bleeding episodes, was reported by forty-three patients.

TABLE III. ECTOPIC PREGNANCIES ADMISSION STATUS

Temperature	Cases	Pulse Rate	Cases	Systolic Blood Pressure	Cases	Clinical Shock	Cases
Below 99° F	27	Below 80	8	Below 80 mm Hg	9	On admission	19
99-100°	34	80- 90	25	80- 90	5	One profound died 20 minutes after admission	
100-101°	7	90-100	9	90-100	2	Shock subsequent to admission	3
101-102°	1	100-110	8	100-110	10	No observation of clinical shock	48
Not recorded	1	110-120	2	110-120	12		
		120-above	10	120-130	17		
		Imperceptible	3	130-140	12		
		Not recorded	5	No record	3		

TABLE IV. ADMISSION BLOOD STUDIES

Hemoglobin	Cases	White Cell Count	Cases	Hemoglobin Drop	Cases
Below 40%	2	Less than 9,000	18	Less than 5%	21
40-50	8	9-10,000	9	5-10	16
50-60	16	10-11,000	2	10-15	12
60-70	21	11-12,000	9	15-20	6
70-80	8	12-13,000	3	20-25	9
80-90	14	13-14,000	7	25-30	3
Not recorded	1	14-15,000	3	30-35	0
Sedimentation rate done	26	Over 15,000	18	40%	2
Elevated	16	Unknown	1	Not recorded	1
Not elevated	10				

Rectal pain and/or pain on defecation reported by seventeen patients, is understandable when the findings of cul-de-sac changes are noted. A relatively small number of patients reported no pain, dull pelvic ache only, pain associated with urination, or epigastric pain.

Abdominal examination revealed tenderness of some kind in sixty-eight instances, rebound tenderness occurring in fifty-eight of these. Abdominal distention was present in fifteen instances, and rigidity in twenty-three instances. Abdominal mass or masses were recorded in eight instances. Pelvic examination revealed adnexal mass or masses in thirty-eight patients. In most of these reports, the masses are described as very tender. Adnexal tenderness without definite masses was reported in seventeen patients. In many patients, masses could not be outlined because of extreme tenderness. Cul-de-sac fullness or masses were described in thirty-four patients, and cul-de-sac tenderness without fullness in nine patients. Painful cervix was reported in forty patients, the most frequent description being extreme pain on movement of the cervix. The cervix was reported as soft and/or bluish in twenty-seven patients. The uterus, when palpable, was described as enlarged in twenty-one patients, and tender in nineteen patients.

Admission temperature was recorded in sixty-nine cases. It was found to be below 90 degrees F. in twenty-seven cases, 99 to 100 degrees in thirty-four cases, 100 to 101 degrees in seven cases, and 101 to 102 degrees in one case. The admission pulse rate, recorded for sixty-five patients, was below 80 in eight patients, 80 to 90 in twenty-five, 90 to 100 in nine, 100 to 110 in eight, 110 to 120 in twenty-two, above 120 in ten patients, and three patients were reported to have imperceptible pulses. Systolic blood pressure was recorded on admission in sixty-seven instances. The pressure was below 80 mm. Hg in nine instances, 80 to 90 in five instances, and 90 to 100 in two instances. The remainder of the admission readings varied from 100 to 140 mm. Hg. Clinical shock was noted on admission in nineteen patients; one patient, admitted in profound shock, expired twenty minutes later. Subsequent clinical shock developed in three patients who were not admitted in shock.

Admission hemoglobin determinations are reported in per cent since that is the method used at the hospital during most of the period covered by this study. Two patients had admission hemoglobin determinations below 40 per cent, eight had 40 to 50 per cent, sixteen had 50 to 60 per cent, twenty had 60 to 70 per cent, eight had 70 to 80 per cent, and fourteen had 80 to 90 per cent hemoglobin. Maximum hemoglobin drop was calculated. Twenty-one patients had less than 5 per cent drop, sixteen had 5 to 10 per cent, twelve had 10 to 15 per cent, six had 15 to 20 per cent, nine had 20 to 25 per cent, three had 25 to 30 per cent, and two had 40 per cent hemoglobin drop.

The admission white cell count varied widely. Eighteen patients had a count of 9,000 or less,

nine patients had 9,000 to 10,000, two patients had 10,000 to 11,000, nine patients had 11,000 to 12,000, three patients had 12,000 to 13,000, seven patients had 13,000 to 14,000, three patients 14,000 to 15,000, and eighteen patients had a count of over 15,000. Factors influencing white cell count and hemoglobin were dehydration, blood loss and administration of intravenous fluids, plasma and blood.

Twenty-eight patients had had lower abdominal or pelvic surgery previous to the onset of the present illness. There had been one tubal ligation (Madelaner), eighteen appendectomies, four dilations and curettages, one uterine suspension, one excision of a Bartholin cyst, two vaginal plastic operations, one cesarean section, and six procedures for ectopic pregnancy, and one salpingectomy for reasons other than ectopic pregnancy.

History and/or evidence of pelvic inflammatory disease was found in forty-two patients. There were histories and operative findings of pelvic inflammatory disease in nineteen patients, operative findings only in twenty-two patients, and history but no operative findings in one patient. In some cases there was operative description of pelvic inflammatory disease without any pathological confirmation.

There were nineteen positive Friedman tests, and several cases in which the test results were not recorded. Posterior colpotomy or colpopuncture was positive in twenty cases, equivocal in one, and negative in five cases. Culdoscopy was done once.

Dilation and curettage was carried out on twelve patients. Decidual tissue was obtained six times, hyperplastic endometrium twice, proliferative endometrium twice, secretory endometrium once and insufficient tissue for diagnosis once.

The time interval from admission to surgery varied from less than one hour to sixteen days. The interval was less than 3 hours on thirteen occasions, 3 to 5 hours in eight cases, 5 to 7 hours in five cases, 7 to 9 hours in three cases, 9 to 11 hours in two cases, 12 to 24 hours in eight cases, 24 to 36 hours in three cases, 36 to 48 hours in one case, and 48 hours to 16 days in twenty-six cases. One patient expired twenty minutes after admission. Several patients were discharged and re-admitted prior to surgery.

Summary

1. A review of the symptoms and diagnostic findings of seventy ectopic pregnancies has been presented. This series is not to be considered as typical of ectopic pregnancy, but of ectopic pregnancy as encountered in indigent patients at the Minneapolis General Hospital.

2. The percentage of patients admitted in shock was almost identical in the two Minneapolis General Hospital series: 27.1 per cent in this series, and 27.4 per cent in Dr. Sadler's series.

3. Of these seventy ectopic pregnancies, 60 per cent (forty-two cases) were complicated by or associated with pelvic inflammatory disease in some manner. This particular phase of the study cannot be compared with Dr. Sadler's series because he included only those diagnoses of inflammatory disease verified by tissue study, whereas this study also includes diagnoses based on operative findings alone.

4. The high incidence of recurrent ectopics

(six cases) (8.6 per cent) may further illustrate the increased incidence of ectopic pregnancy in the inflammatory pelvis.

5. Study of the data on vaginal bleeding reveals wide variation with no predominant pattern; however, fifty-eight of the seventy patients (83 per cent) presented some type of abnormal bleeding associated with pain.

6. The high incidence of rebound tenderness, distention, cul-de-sac masses, adnexal masses and shoulder pain illustrates the marked pathologic processes in this series.

7. Admission hemoglobin levels and drops in hemoglobin were undoubtedly influenced by dehydration, blood loss and transfusions administered.

8. The long interval between admission and surgery in twenty-six cases illustrates the need for more rapid diagnosis. Culdoscopy might have shortened this interval, but this procedure must be undertaken with great care in the inflammatory pelvis.

Note: Final diagnosis recorded on these patients: ruptured tubal pregnancy, forty-eight; tubal pregnancy with probable rupture, nine; aborting or aborted tubal pregnancy, five; unruptured tubal pregnancy, seven; ectopic pregnancy, probable ovarian, one.

OBSTRUCTION OF THE BOWEL IN THE NEWBORN

(Continued from Page 169)

revealed that distal loops of bowel beyond the ligament of Treitz were completely collapsed. There was meconium in the colon. The proximal duodenum was distended and the distal duodenum was collapsed. The diagnosis was annular pancreas. A retrocolic duodenal jejunostomy side-to-side anastomosis was performed. The child died November 11, 1950, twenty-two days after surgery. Autopsy revealed malformation of duodenum, pneumonitis, and necrosis of the brain. The anastomosis was functioning all right.

Summary

Six causes of bowel obstruction in the newborn, together with two case reports, have been presented. Various diagnostic points have been given. However, the important thing is not to differentiate the type of bowel obstruction as to etiology, but as to whether it is a complete obstruction, and whether it is a high or low bowel obstruction. The sooner this is done after birth, the better the prognosis for the child.

Athletic Accident Benefit Plan, 1954-1955

WILLIAM E. PROFFITT, M.D.
Minneapolis, Minnesota

IN JANUARY, 1952, a summary and explanation of the Athletic Accident Benefit Plan of the Minnesota State High School League, its limitations, administration, and methods of financing, was presented to the members of Hennepin County Medical Society in their *Bulletin*. At the time of this writing an up-to-date review with new revisions in this program is being announced to all of the member doctors of the Minnesota State Medical Association.

In spite of conscientious efforts by H. R. Peterson and by the State High School League, there resulted some controversies between Minnesota doctors and the league, mostly because of an honest lack of knowledge on the part of either the student athlete and his family or the doctor himself. There was a feeling by the parents that the payments by the league were *full* and satisfactory for medical care of the injury involved. There was an unfortunate misunderstanding by some doctors in the state that an attempt was being made by the state league to set up a fee-schedule for athletic injuries and that payments were too low. Fortunately huge strides have been made to eradicate both of these misunderstood aspects in the program.

The Medical Service Committee of the Minnesota State Medical Association has worked for several years in close co-operation with H. R. Peterson, executive secretary of the Minnesota State High School League, and feels that your committee is very close to a satisfactory solution. During this period, Mr. Peterson and his Board of Control have raised a great number of the benefits paid, especially on the common type of athletic injuries. They have devised a completely new method of perforated forms in order to attempt a more certain method of dispersing the information about the "benefit" plan, not insurance, to the student athlete and his parents. Printed on the Parents Permit Signature Card is the following statement "The undersigned further states that the 'Notice to Athletes and Parents' has been received; and understands the Benefit Plan provides only limited financial assistance; and the balance of any bill, if not paid in full, is a responsibility of the pupil or his parents."

The extremely controversial paragraph in the old explanatory bulletin read, "The plan provides limited coverage only: The schedule of maximum allowances *grants reasonable payments for normal services.*" This has been removed from the new forms and only the following paragraph used: "One of the major services provided by the League is the Athletic Benefit Plan which offers financial assistance in meeting the cost of medical, dental, and hospital services resulting from injuries incurred while participating in athletic activities sponsored by the school. The plan is a non-profit mutual benefit program and not insurance. It provides specific limited allowances for various injuries, and the balance of the bills, if not paid in full, is a responsibility of the athlete or his parents". Your committee feels that this should do much to clarify the apparent misunderstanding between the league and the doctors of medicine in the State of Minnesota.

The financing of this plan is done by charging in the past $2 per year to the boy who participates in football and other sports, and $1 per year if he does not participate in football. This fee was known to be insufficient for sound underwriting but many boys in the state from some of the less fortunate families have been unable in the past to afford even this fee. The deficit of the underwriting was made up from profits of the Minnesota State High School Basketball Tournament each year. Fortunately for the success of the plan, the weather and competition have co-operated to make a financially successful basketball tournament. However, realizing that this was not sound and there could be "many a slip 'twixt the cup and the lip", the Board of

Seminar

DIAMOX

ELLIOT M. LATTS, M.D.
Minneapolis, Minnesota

Diamox (2-acetylamino-1, 3, 4 thiadiazole-5-sulfonamide) is a heterocyclic sulfonamide which was developed by the American Cyanamide Company in the search for a powerful carbonic anhydrase inhibitor related to sulfanilamide. In 1940, Mann and Keilin[17] discovered that sulfanilamide and other compounds with a free sulfonamide group inhibit carbonic anhydrase activity. An amino group in the para position was found necessary for the antibacterial action but was not necessary for the inhibitory effect on carbonic anhydrase (Fig. 1). Following the observation that sulfanilamide induced acidosis with an alkaline urine,[21] Höber[14] suggested that alkalization of the urine was due to inhibition of carbonic anhydrase in the renal tubules. Subsequently, Pitts and Alexander[24] showed that sulfanilamide reduced the capacity of the kidney to eliminate acid under maximal stimulation by a phosphate buffer load.

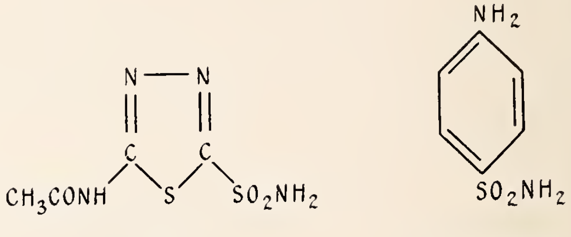
In 1949, Schwartz[26] administered sulfanilamide to three patients with congestive heart failure and observed an increased excretion of sodium, potassium, and water. Although clinical improvement and reduction of edema was noted, the drug was considered to possess too little carbonic anhydrase activity and to be too toxic for continued use.

Chemistry and Pharmacology

Diamox is 40 to 500 times as potent a carbonic anhydrase inhibitor as sulfanilamide. The pharmacological properties have been described by Maren and co-workers.[18,19,20] (Fig. 1.)

Diamox is well absorbed from the gastro-intestinal tract in both the experimental animal and man. It possesses very low systemic toxicity and is excreted largely unchanged by the kidney in twenty-four hours. The renal clearance is approximately two-thirds that of the glomerular filtration rate in the dog. Studies with Diamox and carbonic anhydrase both *in vivo* and *in vitro*, show that the interaction between inhibitor and enzyme is reversible.

Following a single oral dose, there is increased urinary excretion of sodium, potassium, bicarbonate and water. The pH of the urine increases and titratable acid and ammonia excretion are sharply reduced or abolished. This effect lasts about six hours and then reverses with the onset of the recovery phase. This phase lasts about eighteen hours and is marked by urine almost free of bicarbonate and sodium, low in potassium, and with increased titratable acid and ammonia. There is a drop in plasma bicarbonate and pH during the diuretic phase which returns to normal during the recovery period. This effect in the rat is largely independent of the dose in the range of 10-1000 mg./kilo. Dogs given 100 mg./kilo/day for sixteen months showed an initial renal response but then the urinary pattern reverted to normal after the first few days although there was a sustained acidosis characterized by a low blood pH and plasma bicarbonate and elevated chloride. The serum sodium and potassium remained normal. Urinary and plasma electrolytes reverted to normal in three to four days following withdrawal of the drug. If the dog was then challenged with Diamox, the response was the same as with initial treatment. These results were in contrast to those in dogs maintained on 5 to 10 mg./kilo/day where there was a continued renal effect and little or no acidosis. On low daily doses extra base output was effectively countered by extra base conservation during the recovery periods. On high or multiple doses the animal became refractory to the diuretic effect and remained acidotic. The drug is not cumulative with long-term administration and has no preference for any tissue, except red cells, which it appears to saturate at a fairly low level.



Diamox Sulfanilamide

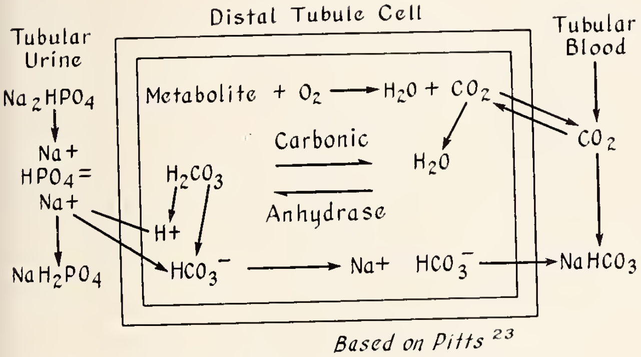
Tomashefski et al[30] and Carter[8] have found after the intravenous administration of Diamox to dogs that the alveolar P_{CO_2} was significantly less than the arterial P_{CO_2}. Shepard et al[28] reported similar findings in two normal human subjects after exercise. These findings are thought to result from interference with the release of carbon dioxide from pulmonary capillary blood after inhibition of carbonic anhydrase.



Based on Pitts [23]

Fig. 2. Process of acidification by renal tubule.

Diamox exerts a marked inhibitory effect on pancreatic secretion in the dog following stimulation with secretin.[5] It has also been shown both in dogs[15] and ulcer patients[29] that Diamox causes a significant inhibitory effect on hydrochloric acid production.

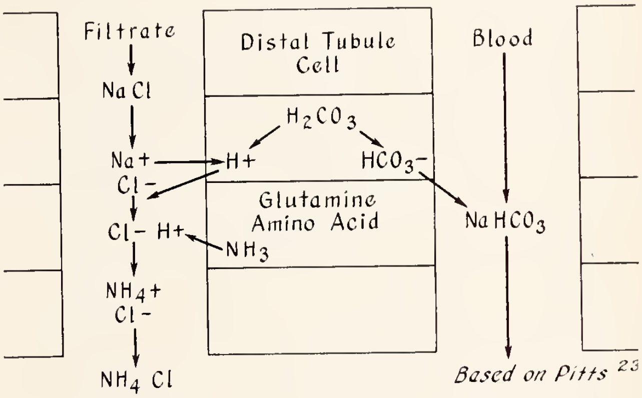
Mechanism of Action

In order to understand better the renal action of Diamox, a brief discussion of acid-base balance by the kidney will be presented. Two hundred liters of plasma are filtered through the glomeruli each day. Each liter of plasma contains approximately 25 mM. of bicarbonate. The total bicarbonate filtered is 5,000 mM., which is five times the body store of bicarbonate.

Obviously the bicarbonate must be filtered over and over again and reabsorbed each time by the renal tubules as only 1 to 2 mM. escapes into the urine each day. Sulfuric and phosphoric acids are formed in considerable quantities in the metabolism of phospholipids and proteins. The excretion of titratable acid and ammonia reverse the process of neutralization and promote the elimination of acid anions minus the base. These two renal mechanisms prevent exhaustion of the bicarbonate stores.

Carbonic anhydrase accelerates the reaction of carbon dioxide and water to form carbonic acid in the tubule cells. The ionization of carbonic acid to form hydrogen and bicarbonate ions provides hydrogen ions which are exchanged for sodium ions of the buffers of the glomerular filtrate, chiefly in disodium phosphate (Na_2HPO_4) and sodium bicarbonate ($NaHCO_3$). The excretion of sodium acid phosphate (Na_2HPO_4) in the urine conserves sodium which returns to the blood. (Fig. 2).

Ammonia (NH_3) is formed from glutamine and other amino acids in the distal tubule cell. Each molecule of ammonia secreted into the tubular urine binds one mole of hydrogen and permits one mole of sodium to be reabsorbed. Thus ammonia is exchanged for base, meq. for meq., although the exchange is indirect (Fig. 3). The rate of ammonia excretion is inversely proportional to the pH of the urine; i.e., the more acid the urine, the more ammonia is excreted, and vice versa.



Based on Pitts [23]

Fig. 3. Process of ammonia production by the renal tubule.

Inhibition of carbonic anhydrase in the kidney leads to the following:

1. Decreased urine acidity due to decreased availability of hydrogen ion from carbonic acid.

2. Increased urinary excretion of sodium due to decreased sodium reabsorption.

3. Increased urinary excretion of potassium due to increased tubular secretion of potassium. Berliner[3] has shown that potassium ions compete with hydrogen ions in the tubules for excretion; hence decreased hydrogen ion secretion leads to an increased potassium output.

4. Decreased ammonium excretion due to limited availability of hydrogen ion for combination with ammonia. This also leads to increased excretion of sodium.

5. Increased total carbon dioxide content of the urine due to increased excretion of bicarbonate. Normally, hydrogen ion secreted by the renal tubule cell reacts with bicarbonate in the tubular urine and the carbon dioxide evolved diffuses back into the blood. When hydrogen ion secretion is blocked by carbonic anhydrase inhibitor this reaction does not take place and bicarbonate excretion is therefore increased.

Clinical Applications of Diamox

Friedberg, Halpern and Taymor[12] studied the intravenous effect of Diamox on twelve hospitalized and ambulatory patients with congestive heart failure of varied etiology and on three patients without evidence of cardiovascular or renal disease. All of the cardiac patients had been treated in the previous few weeks and had little evidence of edema except one patient who had moderate edema of the lower extremities. A single intravenous injection of 0.75 gm. of Diamox was given. Urinary output increased in each case, and the urine contained increased amounts of sodium, potassium, and bicarbonate. Chloride and phosphate excretion were only slightly increased and appeared to be related to the increased urinary flow. The urine became alkaline about thirty minutes after injection and remained so for a period of about six hours. Titratable acid rapidly disappeared. Urinary ammonium was markedly diminished in all cases; however, it continued to be present even when the urine was more alkaline than the plasma. The sodium excretion increased markedly in every instance independent of the presence or absence of congestive heart failure. In two of the control subjects who received 5 to 7 grams of salt a day, the sodium excretions increased four to six times over the control values. In the other control subject on a 500 mgm. sodium diet, there was a tenfold increase in sodium excretion over the control value. No significant effect was noted in plasma concentration of sodium, potassium, chloride, phosphate or creatinine. There was a slight and inconstant tendency towards a mild acidosis as indicated by a decrease in plasma bicarbonate level and blood pH.

Leaf, Schwartz, and Relman[16] performed balance studies on five patients with congestive failure and on one normal subject before and after the oral administration of Diamox in varying dosage schedules. Two of the patients with congestive heart failure and the normal subject demonstrated the usual responses. The other three patients lost no sodium and responded only with increased potassium excretion and reduction in urine acidity. Unresponsiveness to the drug developed rapidly even with intervals of one to two days between doses, and in one case appeared after a single dose of 0.25 gm. They noted that the onset of drug resistance was always associated with the development of hyperchloremic acidosis.

Friedberg et al[13] studied the oral effect of Diamox in twenty-six patients with various types of heart disease and found an increased excretion of sodium and potassium in the urine of all patients regardless of clinical response. There was slight to moderate increase in chloride excretion in sixteen patients and a decrease in eight. Plasma levels of sodium, potassium, and chloride were not altered significantly. The carbon dioxide content fell in most cases, and in some was accompanied by a slight fall in the blood pH. "Excellent" or "good" clinical responses were claimed in eighteen of the twenty-six patients although the mean weight loss was only 4.4 pounds in the hospital group and 3.8 pounds in the clinic patients. Several dosage schedules were employed, but 0.25 gm. every eight hours for two days and repeated every two to seven days or the daily administration of 0.25 gm. were the most effective. Patients who did not respond to smaller doses did not have a diuresis with larger doses nor did prolongation of the course more than two days produce a diuresis in these patients. In the patients who responded satisfactorily to Diamox, diuresis and weight loss continued until "dry weight" was reached which could be maintained as long as the drug was continued.

Relman, Leaf, and Schwartz[25] reported disappointing results following the oral administration of Diamox in twenty-six hospitalized patients with severe congestive heart failure. Approximately half of the patients failed to lose weight and only one of the remainder became edema free, while the others lost 2 to 6 pounds over a seven-day period. All but three patients had a definite pharmacological effect from the drug even when there was little or no diuretic response. Twelve patients had blood nonprotein nitrogen concentrations of 50-100 mgm. per 100 cc. and in fourteen the level was below 50 mgm. per 100 cc. Only three of thirteen courses of treatment in azotemic patients resulted in weight losses of 4 pounds or more; however, seven of fifteen patients without azotemia had this same response. This suggested to the authors the importance of renal function. The explanation of this response is not clear, but it was postulated that carbonic anhydrase is less important for the over-all reabsorption of bicarbonate when the glomerular filtration rate is low and the filtration of bicarbonate is reduced. Another possibility considered was that the azotemia was simply a reflection of severe circulatory insufficiency and therefore of the factors operating to retain sodium. In spite of the disappointing results the authors refer to some encouraging studies[27] in the treatment of congestive heart failure due to chronic cor pulmonale where Diamox appeared to effect large diuresis and significant clinical improvement.

Belsky[2] reported a definite diuresis in all of thirteen patients with congestive heart failure treated with oral Diamox. Eleven of the thirteen patients were kept edema-free with more or less constant weight on a daily dose of 0.5 gm. of Diamox, low salt diet and digitalis. He noted that Diamox alone or in combination with mercurial diuretics had little diuretic effect in the presence of anascarca or renal decompensation in two patients. However, after removal of ascitic fluid, the effectiveness of Diamox appeared to be increased, although supplementary mercurial injections were required.

Nadell[22] reported on the effect of Diamox in two patients with respiratory acidosis and two normal subjects. In three of four patients, the arterial pH fell by 0.1 to 0.2 pH units. After three days, the urine pH and electrolyte values returned to control values and remained unchanged even when the drugs were given for periods of twenty-five to fifty-five days. However, during the entire period the arterial carbon dioxide was decreased 5-10 mEq/1. The control patients remained asymptomatic during the entire period. One of the two patients with respiratory acidosis continued to be alert outside of the respirator on two separate occasions while getting Diamox. When the drug was discontinued, a more marked respiratory acidosis developed. The other patient developed marked drowsiness fourteen days after therapy was begun. This cleared when the dosage was decreased from 10 to 5 mgm. per kilo.

Fishman, Samet, and Cournand[11] found a diminished ventilatory response following an increase in inspired carbon dioxide in patients with pulmonary emphysema with carbon dioxide retention as compared with emphysematous patients without carbon dioxide retention and with normals. The emphysema patients with carbon dioxide retention were given Diamox over a fifteen-month period. Although the arterial P_{CO_2} and alkali reserve returned to normal there was no improvement in the ventilatory response to carbon dioxide.

Bergstrom[4] et al reported on the effect of Diamox in forty-two epileptic persons with intractable seizures. The rationale underlying such therapy is the production of a mild metabolic acidosis similar to that produced by ketogenic diets. Ninety to one hundred per cent seizure control was obtained in four instances and 50 to 90 per cent in four others. None was made worse. The authors concluded that Diamox is useful in only a small number of cases refractory to other measures.

Becker[1] treated nineteen patients with glaucoma with single doses of 0.5 to 1.0 gms. of Diamox. In all cases, the intraocular pressure began to decrease in 60 to 90 minutes. It reached a minimum in three to five hours and returned to initial levels in eight to twelve hours. Because of the high concentration of bicarbonate in the posterior chamber it was postulated that carbonic anhydrase plays an essential rôle in the formation of aqueous humor. It was not determined whether its mode of action is to inhibit the secretory mechanism directly or whether the fall in intraocular pressure is secondary to induced systemic electrolyte alteration.

Diamox has been tried in the treatment of several conditions associated with edema formation. The impaired renal function in chronic glomerulonephritis probably interferes with the effectiveness of Diamox as a diuretic. However, since it had not proven dangerous, it was thought to be worthy of a trial.[9] Equivocal results have been obtained in the treatment of cirrhosis.[6,7]

Toxicity

No serious toxic effects have been reported with Diamox. Paresthesias of the face and hands and drowsiness have been observed frequently and appear to be related to the dosage.[2,4,13] These side effects have been encountered when the daily dose of Diamox was 1.0 gm. or more and were reduced to a minimum or disappeared when the dose was decreased to 0.5 or 0.25 gm. per day. Bergstrom et al[4] reported fatigue, flushing, polydipsia, hypernea, paresthesias, and headache with doses of 10 to 30 mg. per kilo in the treatment of epileptics. but did not state the number of cases involved. A few instances of disorientation and irrational behavior have been observed in cirrhotic patients treated with Diamox.[10] No instances of renal damage, hematologic disturbances* or skin manifestations have been reported.

Summary

Diamox is a potent carbonic anhydrase inhibitor affecting carbonic anhydrase contained in red cells, kidney, stomach, pancreas, and eye. The usual pharmacological response is characterized by the diuresis of an alkaline urine containing increased amounts of sodium, potassium, and bicarbonate and a decreased plasma bicarbonate and blood pH.

The results of Diamox administration in various disease states have been reviewed. The drug is effective both orally and via the intravenous route. The toxicity is low and consists mainly of paresthesias and drowsiness.

Further clinical trial appears warranted.

LIMITATIONS OF THE WIDAL TEST

HENRY BAUER, Ph.D.
Minneapolis, Minnesota

THERE are three reasons why it is necessary to re-evaluate the Widal test as a laboratory aid in the diagnosis of typhoid fever: (1) knowledge regarding the antigenic relationship of Salmonella typhosa (Eberthella typhosa) to many other Salmonella organisms; (2) the Widal test is essentially of no diagnostic value in the increasingly large number of persons who have had inoculation with typhoid and paratyphoid A and B vaccine; (3) the incidence of typhoid infection in Minnesota is low.

Typhoid O (somatic) and typhoid H (flagellar) antigens are used in the quantitative Widal test. There are approximately 63 Salmonella organisms that possess one or more of the somatic antigens found in S. typhosa. Accordingly, a person who may be infected with and produce antibodies to any one of these organisms gives a satisfactory titer when his serum is tested with O antigen. For example, we have not infrequently demonstrated O antibody titers as high as 1:1,280 in serum from patients with enteric infection and have isolated only S. enteriditis from the stools of these patients. The high O antibody titer in these patients can be easily explained since S. enteriditis possesses two somatic antigens identical to those of S. typhosa.

It is frequently stated that during the early stages of typhoid infection the O titer is higher than the H titer and that a high O titer is diagnostic of typhoid fever. We cannot agree with this statement. The high O antibody titer may be due to an organism with somatic antigens identical to the somatic antigens of the typhoid bacillus. We found that H titers in the great majority of cases were higher than O titers in a study of agglutination reactions in serum from 103 persons reported to be ill with typhoid fever. Also negative results were found in 5.8 per cent of the O tests in this study as compared to negative results in only 1.0 per cent of the H tests. In a study of the agglutination pattern of forty-seven ill patients diagnosed as having typhoid fever and from whom S. typhosa was isolated, the H antibody titer in the great majority of patients was higher than the O titer; in two patients there was no demonstrable O titer, only H agglutinins being detectable.

Thus it would appear that perhaps the H antibody titer would offer more certain aid in the diagnosis of typhoid fever. A study of the H and O antibody titers on serum from 8,945 ill persons who did not have typhoid fever showed that the H antibody titer was consistently higher than the O titer. This was particularly true of serum obtained from 787 persons who had received typhoid vaccine. In this vaccinated group, the results in 43 per cent of the H agglutination tests were positive in dilutions of 1:320 or more, whereas only 2.4 per cent of the O agglutination titers fell in this range. Negative results of H agglutination tests were observed in 24.1 per cent of this vaccinated group as compared to negative results in 55.6 per cent of the O agglutination tests. In a study of serum from 8,075 ill persons who did not have typhoid fever and who gave no history of having had typhoid fever or vaccination, 3.3 per cent of the H agglutination tests gave positive results in dilutions of 1:320 or more, whereas only 0.3 per cent of the O agglutination tests were in this range. Thus it is obvious that we cannot depend on H agglutination as an aid in the diagnosis of typhoid fever.

Perhaps it may be argued that differences in the H and O antibody titers would help in making a diagnosis. Unfortunately no definite single H and O titer is diagnostic of typhoid

---

This is the twenty-fifth in a series of editorial reports sponsored by the Minnesota Society of Clinical Pathologists and designed to foster closer relationships between clinicians and pathologists.

Dr. Bauer is Director, Division of Medical Laboratories, Minnesota Department of Health.

fever. The higher the titer chosen for the diagnostic dividing line, the more likely is such titer to indicate infection but at the same time the smaller will be the number of cases of typhoid thus diagnosed.

We may try to get some value out of the Widal test as a diagnostic aid by testing serial specimens of blood for H and O antibodies. Again we are frustrated by persons who may have had typhoid fever and by the great many people who have received typhoid vaccine. No diagnostic value can be placed on the H agglutinins in a vaccinated person or a person with a history of previous typhoid fever. Even a considerable increase in titer is of little or no diagnostic importance since this may be due to nonspecific causes. No reliance can be placed on O agglutinins since other organisms share common O antigens with S. typhosa. A blood culture done early in the disease would give specific results and in a shorter period than would Widal tests done on a series of specimens of blood.

Since the Widal test is of questionable value in the specific diagnosis of typhoid fever and of no diagnostic value in vaccinated or previously infected persons, we might ask if it is of value in the detection of typhoid carriers. Serologic studies were done on thirty-seven bacteriologically proved typhoid carriers. Nineteen of these carriers (51 per cent) were negative when tested with O antigen including seven who were also negative when tested with H antigen. Eighteen (49 per cent) of the thirty-seven carriers tested showed both H and O antibodies, but the H antibody titers were higher. Although H agglutinins were present more frequently and in higher titer than were O agglutinins in these proved carriers, the same was found to be true in examination of serum from 229 well persons who gave a history of typhoid vaccination, from twenty-eight persons who gave a history of previous typhoid infection and from 2,355 persons who gave no history of vaccination.

Conclusions

1. No arbitrary titer of either H or O agglutinins can be accepted as diagnostic for typhoid fever.

2. Since Salmonella typhosa shares common O antigens with other Salmonella organisms, the O agglutination test is not specific for typhoid.

3. The Widal test is of no practical value in the diagnosis of typhoid fever in vaccinated persons or those with a history of previous typhoid fever.

Recommendations

1. If typhoid or paratyphoid infection is suspected, culture of blood and stools should be done early in the illness. Blood for culture should be collected during the first two weeks of illness. Examination of stools is the procedure of choice after the first two weeks of illness.

2. Stools should be submitted for culture from all persons having enteric infection suggestive of salmonellosis or shigellosis.

3. Since Salmonella typhosa must be isolated from suspects to prove their carrier status, it is thought that examination of stools from the following persons will yield more productive results than will the Widal test: (1) those giving a history of typhoid fever; (2) those who have resided with or prepared food for any persons who have contracted typhoid fever; (3) those who have symptoms suggestive of gallbladder disease; (4) food handlers who, in addition to any of the conditions just mentioned, may give a history of a recent intestinal upset of any nature.

REVIEWS OF MEDICAL MOTION PICTURES

The Committee on Medical Motion Pictures of the American Medical Association announces that Booklet 6 of Reviews of Medical Motion Pictures is now ready for distribution. This booklet contains sixty-four critical reviews of medical and health films which were published in *The Journal* during 1954.

A copy has been sent to the secretary of each state medical society and the books are available to county medical societies from the Committee on Medical Motion Pictures. Other requests should be sent to the Order Department, American Medical Association, 535 North Dearborn Street, Chicago 10, Illinois.

The price of individual booklets is 25 cents each or the complete set of six booklets including all reviews published since 1946 is available for $1.00.

CASE PRESENTATION

DONALD F. GLEASON, M.D.
Minneapolis, Minnesota

Clinical History

A fifty-three-year-old bartender was first admitted to this hospital for treatment of seborrheic dermatitis and for injection of varicose veins, January 30, 1942. He stated that for six weeks he had been receiving intravenous and intramuscular injections, but did not know for what purpose. His blood pressure was 132 mm. Hg systolic and 80 mm. diastolic. Urinalysis showed no abnormalities. The blood Wassermann test resulted in negative findings.

On April 14, 1951, the patient, now aged sixty-two, was admitted to the hospital complaining of epigastric pain for three weeks. Five weeks prior to admission, he had been awakened by a severe constrictive retrosternal pain which extended into his left arm. He was hospitalized elsewhere for two weeks at bed rest. Thereafter, he had no appetite and had suffered three or four attacks of severe colicky pain in the epigastrium which extended across the right upper abdomen and to the right scapular area. He believed that these attacks were caused by eating fried or greasy foods. At times, he had nausea and vomiting during the attack. There had been no chills, fever, jaundice or darkening of the urine.

For three years, he had experienced substernal pain extending into the left arm on exertion, promptly relieved by rest or nitroglycerin. For a year, he had some dyspnea on exertion but no orthopnea nor paroxysmal nocturnal dyspnea. He had had gonorrhea forty years ago but denied having had syphilis. He had been drinking alcoholic beverages excessively for several years.

His mother had died of "heart trouble" at fifty-eight years, his father had died of a "stroke" at fifty-eight years, and one brother had died of "heart trouble" at forty-two years.

The patient was well developed, well nourished and in no acute distress. The pupils reacted normally. The temperature was 98.6 degrees F., the pulse rate 84 per minute. The lung fields were normal to percussion and auscultation. The heart sounds were of good quality and no murmur was heard. The aortic second sound was louder than the pulmonary sound. The point of maximal impulse was in the fifth interspace at the anterior axillary line. The blood pressure was 170 mm. Hg systolic and 116 mm. diastolic. The abdomen was normal apart from moderate epigastric tenderness. Neurological examination showed no abnormalities.

The hemoglobin was 11.3 grams per 100 ml., the leukocyte count 7,250 per cu. mm. (65 per cent neutrophils, 33 per cent lymphocytes and 2 per cent eosinophils), the erythrocyte sedimentation rate 60 mm. at one hour. Specific gravity of the urine was 1.014, the sediment contained 0 to 3 erythrocytes and 0 to 1 leukocyte per high power field, the test for albumin was 1 plus. A catheterized urine specimen showed 15 per cent excretion of phenolsulphonphthalein in one-half hour. The blood Wassermann test was negative, the Kahn 3 plus, the Hinton 4 plus, the VDRL slide test positive in 1 to 2 dilution. Examination of the spinal fluid on two occasions was completely negative, including total protein, complement fixation and gold curve. There was 7.2 per cent retention of bromsulfalein at forty-five minutes, the cephalin flocculation test gave negative findings, the thymol turbidity 5.2 units, the serum bilirubin 0.1 mg. per 100 ml. at one minute and a total of 0.5 mg. A two-hour urine urobilinogen was within normal limits. The blood urea nitrogen ranged between 16 and 25 mg. per 100 ml., the total protein was 6.9 gm. per 100 cc. (3.9 albumin and 3.0 globulin). Five stools showed no occult blood. The serum amylase was 56 units.

The posteroanterior radiograph of the chest showed a left ventricular cardiac contour, marked dilatation of the ascending aorta, tortuosity of the descending aorta and fluoroscopy confirmed the presence of calcification within the ascending aorta. An upper gastrointestinal series and cholecystogram were negative. Barium enema showed numerous diverticula in the lower colon. Radiographs of the skull showed calcification in the vessels of the circle of Willis. An electroencephalogram showed abnormalities, but with no specific connotation. Electrocardiograms showed left axis deviation, sagging ST and negative T in V5 and V6.

Shortly after admission, the patient experienced an episode lasting for two hours, characterized by numbness and weakness of the left arm. There was definite transient weakness of the left forearm during that time, but no abnormal neurological signs were demonstrated either during or after this episode. Throughout his course, he complained constantly of a severe, generalized headache which was not relieved by codeine. There was anorexia and occasional nausea and vomiting not described as projectile. Within five weeks, he had lost 12 pounds in weight. On the morning of June 24, he was found to be comatose, gasping, cyanotic and promptly expired.

Discussion

Dr. Smith: For three years, this man, now sixty-two, experienced substernal pain which extended into the left

---

From the Minneapolis Veterans Hospital; Dr. Gleason, pathologist.

arm on exertion and which was promptly relieved by rest or nitroglycerine. For a year, he had some dyspnea on exertion but neither orthopnea nor paroxysmal nocturnal dyspnea. This, of course, is the classical description of angina pectoris. To me, it means that the man has myocardial ischemia. There is a host of diseases which will cause myocardial ischemia, the most important of which is coronary artery disease, and it is by far the most common cause in our "macro-molecular" human population.

Five weeks prior to admission, he had been awakened by a severe constructive retrosternal pain which extended into his left arm. He was hospitalized elsewhere for two weeks' bed rest. Myocardial ischemia occurring during sleep has a different connotation. Ischemia can occur during sleep if an individual has frightening nightmares or if for some reason a hypertensive patient drops his blood pressure to low levels. Most often, it is due to an increment of coronary artery disease, usually thrombosis. If this ischemia is lasting, usually over fifteen to thirty minutes, some myocardial necrosis will occur, and we clinically call it infarction. I assume that the diagnosis of myocardial infarction was made when this patient was hospitalized elsewhere.

Dr. Samuel Nesbitt: That diagnosis was made.

Dr. Smith: The protocol states that he had gonorrhea four years ago but he denied having syphilis. That is a very circumstantial bit of evidence for a diagnosis of syphilis, but he stated he had been treated for six weeks with intravenous and intramuscular injections, although he did not know their purpose. In 1942, the treatment in vogue, of course, was combined mapharsen and bismuth therapy. It would have been possible to confirm this treatment with an x-ray of the gluteal region to look for intramuscular deposition of bismuth. Possibly even now, the radiologist can aid in this problem. Dr. Nesbitt used the past perfect tense here, "he had been receiving." I assume that this was just a short period before admission, and the serological test for syphilis was presumably negative when seen by his physician then. This causes me to wonder what evidence his physician had in 1942 to start this therapy.

Ordinarily, physical examination will help us somewhat in the differential diagnosis of the cause of angina pectoris. There was no evidence of any valvular disease. He did have hypertension and, of course, hypertension tends to accelerate atherosclerosis. The blood Wassermann test gave negative findings, the Kahn was 3 plus, the Hinton 4 plus and the VDRL slide test positive in 1:2 dilution. We have already some presumptive evidence that this man had syphilis and I will add this as very strong evidence. In late syphilis, this discrepancy is seen fairly commonly—complement fixation tests being negative while macro and micro flocculation tests are positive. If we were seeing this patient today, perhaps treponema immobilization tests would be of value.

The posteroanterior radiograph of the chest showed a left ventricular cardiac contour. There is a discrepancy between the radiograph as just described and the physical examination. I will accept the radiograph in this controversy. I think that physical examination of the heart is a very difficult and sometimes confusing procedure. Further, the radiographic examination showed marked dilatation of the ascending aorta, tortuosity of the descending aorta, and fluoroscopy confirmed the presence of calcification within the ascending aorta. This latter finding I would like to call pathognomonic evidence of lues. It is probably better evidence than a pathologist's examination. A study reported in 1945 by Jackman and Lubert[2] showed that in patients studied at post mortem, in whom the diagnosis of syphilis was possible pathologically, 22 per cent had calcification of the ascending aorta. Two patients with a pathological diagnosis of only arteriosclerosis had similar calcification. In one of these, there was serologic but no pathologic evidence of syphilis. The other patient had very diffuse and extremely severe arteriosclerosis. I think that this is firm evidence. We could pause here and let Dr. Olson show us the radiograph.

Dr. P. A. Olson: The chest radiograph shows the important features which Dr. Smith discussed. There is very distinct linear density in the wall of the ascending aorta which is also dilated to aneurysmal degree. It is sometimes hard to state what is aneurysmal and what is just dilated, but certainly this is wide enough so we would call it aneurysmal. There is calcification in the ascending aorta, so we should certainly consider that lues is present until proven otherwise. The heart as seen in the posteroanterior view shows moderately severe enlargement of the left ventricle. The second shadow, the denser one medial to the left heart border, is the descending aorta. We cannot visualize its right border. Whether he has another aneurysm here is difficult to determine, but the aorta is certainly wider than it should be and is rather tortuous. The gastrointestinal series is normal, save for a diverticulum of the duodenum. This one radiograph of the gall bladder shows that the dye is not concentrated well, but there is no evidence of calculi.

Dr. Smith: The electrocardiogram showed left axis deviation, sagging ST and a negative T in V 5 and V 6. In addition, he has very low R waves across the anterior precordium. I would interpret these changes as subendocardial damage which might have well extended transmurally, anteriorly.

Now, I would like to go back to the reason for his admission. His presenting complaints were in the gastrointestinal system. Examination of the abdomen revealed no abnormalities except for moderate epigastric tenderness. His leukocyte count was normal and the erythrocyte sedimentation rate was 60 mm. There was a 7.2 per cent retention of BSP. The serum amylase was 56 units—I wonder if that was drawn at a time when he was having distress.

Dr. Nesbitt: We do not know.

Dr. Smith: We could see those abdominal x-rays now.

Dr. Olson: We can see marked calcification in this area which is typical of calcified abdominal aorta. The barium enema shows only a few diverticula in the sigmoid and the lower descending colon. There are moderately severe arthritic changes. There is no evidence of bismuth in the buttocks.

Dr. Smith: This brings up the problem of gastrointestinal complaints in patients with heart disease—a discussion about abdominal angina. In a man with a very compromised coronary blood flow, the mere addition of heavy meal may cause distress. One other possibility which has been advanced more frequently recently is that people who have diffuse vascular disease actually have mesenteric artery insufficiency and distress on this basis.

I am unable at this stage to make a diagnosis of hepatic cirrhosis in this man. I do not think there is any strong evidence of intrinsic gastrointestinal disease. Specific gravity of the urine was 1014. He had a 1 plus albumin and 15 per cent excretion of phenolsulphonphthalein in one-half hour. This depression, along with a normal blood urea nitrogen value, is quite a common functional derangement in patients with hypertension with efferent arteriolar constriction.

So now we go to the next complaint. His neurological examination was normal at the time of admission.

He had two spinal fluid examinations completely negative. Did this include dynamics?

Dr. Nesbitt: Yes.

Dr. Smith: A radiograph of the skull showed calcification in the vessels of the circle of Willis. Shortly after admission, according to the protocol, the patient experienced an episode lasting for two hours characterized by numbness and weakness of the left arm. "There was definite transient weakness of the left forearm but no abnormal neurological signs." I think these two statements are mutually exclusive. If he had true weakness, it would have to be listed as neurological, unless it is known to be muscular. I assume it is meant that he had no reflex changes. Throughout his course, he complained constantly of severe generalized headache which was not relieved by codeine. He had vomiting, not described as projectile. He lost 12 pounds in weight. Finally, he was found to be comatose, gasping, cyanotic and promptly expired. Do we know how long before he was found to be comatose that he was last observed?

Dr. Nesbitt: He was seen about an hour before. He was found in distress and he died in a very few minutes after that.

Dr. Smith: This finding of calcification in the vessels of the circle of Willis in a man who has hypertension, is not really very helpful. Camp[2] states that 4 per cent of any given group of people of age sixty would have such calcification. I would like to see those x-rays now.

Dr. Olson: Maybe you can't see it, even from the front row, but there is calcification in the internal carotid artery. There are several other little linear calcified densities in the region of the sella, the exact site of which is not definite but appears to be in vessels. The internal carotid is definitely calcified. The pineal gland is not calcified, so we cannot use it as a landmark as far as shift is concerned. No other abnormality is seen.

Dr. Smith: Well, we have a man with angina pectoris, myocardial ischemia, and luetic aortitis. The problem now is, why does he have coronary artery insufficiency? He did not have aortic insufficiency. Most patients who have ostial involvement of the coronaries have aortic insufficiency. Even when aortic insufficiency is present most patients who have evidence of myocardial ischemia do have coronary artery disease. We have evidence that he has arterial disease elsewhere. I would prefer to think that he has coronary atherosclerosis in addition to his luetic aortitis. He has hypertension, the cause of which we do not know. We know that he was normotensive at the age of fifty-three and that he became rather severely hypertensive thereafter. We do have evidence that this vascular disease is rather far advanced and that he had cardiomegaly otherwise poorly explained; I would prefer to think that his hypertension was of relatively long standing and its cause will not be disclosed. In the kidneys, he should have changes of benign hypertension with or without arteriosclerosis. I mentioned the gastro-intestinal complaints and the fact that I am wavering between abdominal angina and mesenteric artery inadequacy. I think the latter is a possibility when we have demonstrated vascular disease, and he did have, I think, some vascular disease of the lower thoracic and upper abdominal aorta so that there is involvement in the area of the mesenteric artery.

The causes of the cerebral symptoms are very difficult for me to ascertain. There seem to be no localizing findings. We have evidence that the headache was not on the basis of increased intracranial pressure. Since this man was an alcoholic, I would like to consider the possibility of a subdural hematoma. I should think if it were the cause of this man's symptoms, there would be evidence of increased pressure.

Dr. E. T. Bell: Could ischemia of the brain give him headaches?

Dr. Smith: Are you thinking of diffuse ischemia?

Dr. Bell: Yes, I was thinking of a stenotic artery ischemia.

Dr. Smith: Yes, but he has had symptoms for some time, and I'm bothered by ascribing a severe headache to that cause. However, there is the possibility that he had an aneurysmal dilatation of some larger artery intracranially. That could cause headache without increased intracranial pressure. There is really no positive evidence for it and yet I feel that this man's headache has to be explained.

Now can we put all these things together in an Oslerian fashion? As has been done so often in this series, polyarteritis must be raised as a strong possibility. I agree that this is a possibility but I find no evidence for it. For me, it won't explain the headache very well. I think the hypertension is of long standing. It could explain the abdominal pain, but we already have two other reasons for vascular disease, and I dislike raising a third. Dissecting aneurysm should be considered. This could cause pain simulating myocardial infarction and it would give rise to diverse pains and findings elsewhere. I assume that the pulses were palpated and that they were equal. The man already has luetic aortitis. Others have reported that the finding of a dissecting aneurysm superimposed on the luetic aortitis is highly uncommon and actually the former gives some protection against dissection.

Embolization would be one way to put everything together—mycotic aneurysms from SBE or bland emboli from mural thrombus or from arteriosclerotic plaques. I should think, though, that we would have localized findings that are more specific.

I have to state that I am unable to arrive at a definite entity to explain his central nervous system findings, that I would favor an aneurysm of one of the large arteries at the base of the brain which was not seen roentgenographically.

Dr. J. P. Knoedler: Do you think his headache could be due to hypertension?

Dr. Smith: His headache was of an acute onset, his hypertension chronic. I dislike ascribing his headache to hypertension.

Dr. C. N. Sadoff: You said that you prefer to regard the hypertension as a chronic thing and would you then disregard the blood pressure reading in 1942?

Dr. Smith: No, I think that this hypertension probably developed in the interval.

Dr. J. Rothstein: Would you entertain the diagnosis of a slow-leaking cerebral artery aneurysm?

Dr. Smith: I would be worried by the fact that he did not show cerebral spinal fluid changes.

Question from Audience: Would you care to hazard a guess as to the most likely cause of his sudden demise?

Dr. Smith: Yes, I meant to mention it. His hemoglobin had fallen, for reasons not explained, when he came in. I think this amount would be too much for bleeding into the central nervous system. He died very suddenly. It sounds like a cardiac death or death from exsanguination; he is a candidate for either one.

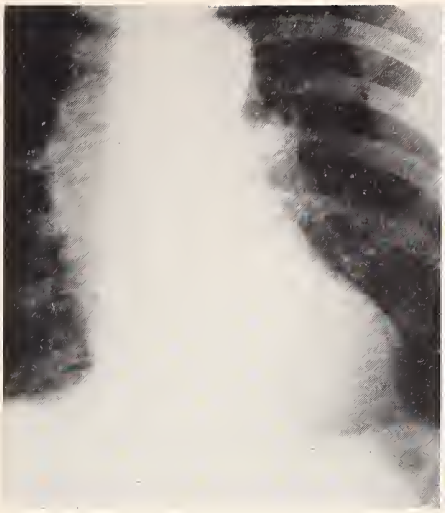

Fig. 1. Chest radiograph, April 16, 1951. Note widened ascending aorta with irregular linear streaks of calcium and second abnormal convex density superimposed behind enlarged left heart border. (Photograph retouched to give more accurate reproduction.)

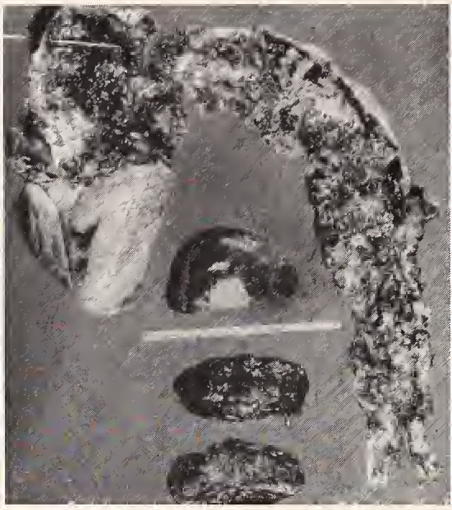

Fig. 2. Heart, aorta and kidneys (one bisected). Severe atherosclerosis of aorta with aneurysmal dilation, ulcerations and mural thrombi. Coarse scars and pitting of kidneys.

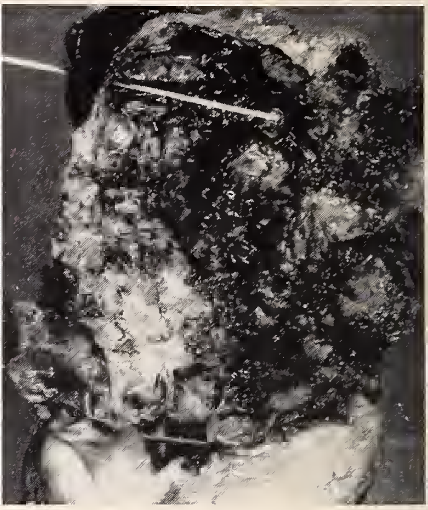

Fig. 3. Heart, aorta, closeup. Severe ulcerating atherosclerosis. Applicator stick in perforation which dissected into pericardial sac.

Dr. Nesbitt: Exsanguination from what?

Dr. Smith: It would be either from the aneurysm in the arch of the aorta or in the descending aorta.

Dr. T. Tamlyn: Do you think that the cerebral difficulties might be explained by meningovascular lues?

Dr. Smith: Well, meningovascular lues should appear relatively early—within five years. If one requires absolute criteria for the diagnosis of vascular lues, he needs to demonstrate the organism. That would be unusual especially since he received some therapy.

Question from Audience: About this radiologic sign of duodenal diverticulum; could that be considered as a perforation into fat rather than a true diverticulum?

Dr. Olson: It's on the lesser curvature of the duodenum. It almost has to be a diverticulum.

Dr. Nesbitt: Clinically, the diagnosis was that of luetic aneurysm. No one hazarded any suggestion on the chart as to the cause of the sudden exitus. The neurologist saw the patient on several occasions and all he offered as the cause of his headaches was "headache following spinal tap," which had been done several times in an effort to determine the cause of his headaches. Shall we read the students' diagnosis?

Dr. E. B. Flink: As a matter of fact, the students' opinions include those diagnoses that Dr. Smith has given. One just diagnosed atherosclerosis and arteriosclerotic heart disease. That's the briefest one. Most of them, though, include syphilitic aortitis with aneurysm. Many felt that the final episode was a cerebral vascular accident rather than cardiovascular.

Clinical Diagnosis

1. Leutic aneurysm.

Dr. Smith's Diagnoses

1. Leutic aortitis and aneurysm.
2. Hypertension, cause unknown.
3. Arteriosclerotic heart disease with coronary arteriosclerosis.
4. Cerebral arteriosclerosis; possible cerebral artery aneurysm.
5. Abdominal angina or mesenteric artery insufficiency.
6. Death from myocardial infarction or exsanguination from aneurysmal rupture.

Autopsy Conference

(October 22, 1954)

Dr. D. F. Gleason: The general autopsy examination revealed significant pathologic conditions only in the heart and aorta. The heart itself weighed 525 grams. The pericardial sac was tensely distended by approximately 750 cc. of blood. The left anterior descending coronary artery was completely occluded by an old, pale fibrotic and calcified process and there was a large area of thinning and scarring of the anterior wall of the left ventricle. The left circumflex coronary artery was approximately 50 per cent narrowed but the right coronary artery showed only minimal atherosclerosis. All of the cardiac valves were normal including the aortic valve. The striking pathologic lesion was in the aorta. The ascending and transverse portion of the arch of the aorta was dilated up to 8 cm. in diameter. This process began a few centimeters above the aortic valve ring. There was a very severe atherosclerosis involving the arch of the aorta and the entire thoracic and abdominal aorta and extending down into the iliac arteries as far as they could be examined. This was a very severe process with ulceration of the intima and patches of mural thrombus from the arch of the aorta to the iliac arteries. The aorta and heart are shown in the accompanying photograph.

From the gross examination alone, as seen in these pictures, we would not be able to make a diagnosis of syphilitic aortitis nor syphilitic aortic valvulitis. There is not a sharp line of demarcation of the process in the thoracic aorta as is usually seen with syphilitic aortitis. The aortic valves are entirely normal and do not show the thickened rolled valve edge nor the separation of the commissures usually found in syphilitic aortitis. However, the changes of atherosclerosis, if superimposed upon leutic aortitis, can obscure completely the changes we require to diagnose luetic aortitis.

The immediate cause of death can be seen in the photograph. There was a small rent in the wall of the aorta some distance from the aortic valve but so located in the ascending aorta that the perforation extended into the pericardial sac. The pericardium contained almost 750 cc. of blood which was partially clotted. The patient undoubtedly suffered an acute cardiac tamponade due to rupture of the aorta into the pericardial sac.

The gall bladder and biliary ducts were normal.

Microscopic examination of sections of the aorta reveals a very severe degree of intimal atherosclerosis which extends deeply into the media and partially destroys it. In addition, there is a perivascular inflammatory infiltrate of lymphocytes and plasma cells around the vasa vasorum in the adventitia of the aorta and occasionally extending a short distance into the media. These are the lesions which are often described as characteristic of syphilis of the aorta but we know that severe atherosclerosis of the aorta can also be associated with such lesions, in the absence of syphilis. Sections of the myocardium confirm the presence of an old scarred infarct due to old occlusion of the left anterior descending coronary artery. In at least one area there are a few chronic inflammatory cells still present, consistent with the clinical duration of the infarct, that is three or four months before death.

Sections of the kidney reveal large irregular areas of atrophic kidney substance related to completely occluded small arteries. Many of these atheromatous lesions contain large "cholesterol clefts." We also see similar occluded arteries in the spleen and pancreas. The kidneys show only mild evidence of hypertension in the form of collagenous intimal thickening of small arteries and arterioles.

Sections of the lung reveal mild acute pulmonary edema and congestion.

Sections of the liver reveal no evidence of cirrhosis.

Gross and microscopic examination of the brain reveals a small area of relatively old encephalomalacia just adjacent to one of the caudate nuclei. This is in a stage of repair which would seem to indicate a duration of a month or two. This may have been partly responsible for the patient's headaches.

Final Anatomic Diagnoses

1. Severe generalized arteriosclerosis.
2. Severe atherosclerosis of the aorta from the ascending portion of the arch out into the iliac arteries.
3. Aneurysmal dilatation of the aorta.
4. Perforation of the ascending portion of the aorta into the pericardial sac.
5. Acute cardiac tamponade due to hemorrhage.
6. Luetic aortitis.
7. Diverticula of the duodenum and cecum and sigmoid colon.
8. Moderately severe arteriosclerotic damage to the kidney.
9. Relatively recent area of encephalomalacia in the brain.

We have to admit that we cannot be certain about the presence or absence of luetic aortitis, but considering all the evidence, we feel that it is probably present.

Dr. Smith: I would like to ask whether the ostium of the superior mesenteric artery was occluded by atherosclerosis.

Dr. Gleason: I am sorry, but that area was not described specifically and I cannot identify it from our gross photographs.

Dr. Bell: I would like to comment upon this aneurysm. When syphilitic aneurysm is overshadowed by massive atherosclerosis like this, we do not know whether syphilis is present or not. We have no criteria to identify it when severe atherosclerosis is present. If you read that some writer diagnoses syphilis or no syphilis in cases like this, I tend not to believe him. I do not believe there is any way to tell them apart. If syphilitic aortitis occurs in a patient without much atherosclerosis, we can make the diagnosis relatively easily. This man has an extremely severe atherosclerosis which has destroyed much of his aorta. That can cause dilation also, but in view of this aneurysm being in the ascending arch and in the presence of positive serology, I believe that the presumption is that this has a syphilitic background to it. Any kind of an aneurysm can rupture.

Dr. Smith: I would like to ask about pain in small cerebral infarcts. I have the impression that the headaches associated with these are not unremitting nor unrelieved by codeine. That bothers me a great deal. I know we do not have an explanation for the headache otherwise. I wish we did.

Dr. Bell: The patient probably had a lot of cerebral ischemia. The headache might be due to that.

Dr. Smith: Other individuals with cerebral ischemia do not usually have headache.

Dr. Flink: Would you say just a word about the causes of sudden death?

Dr. Smith: When sudden death occurs, that is within a few minutes, it is almost always cardiovascular. Death due to lesions of the central nervous system are very infrequently that fast. This patient was observed about half an hour before the comatose state and he died very promptly after that. There are only a few central lesions which will cause sudden death, one being rupture of an aneurysm of the basilar arteries; it is uncommon.

Dr. Flink: Incidentally, one of the students did give rupture of an aneurysm of a basilar artery as the cause of death. We are often faced, in patients of this age, with the problem of explaining an elevated sedimentation rate, in a patient who is otherwise apparently well. Seeing the aorta in this man, I just wonder whether there is not enough thrombotic process and enough ulceration to explain the elevated sedimentation rate. I am sure he had myocardial infarction in the not-too-distant past and he has destruction of tissue in the kidney, but I wonder whether the aorta does not account for the elevation of sedimentation rate in this case.

President's Letter

TO GIVE WISELY

The problem of personal giving to all the many and varied appeals for funds that come, not only to the doctor's office, but to the home of the average citizen of our state, is one that is becoming increasingly more acute. In scores of emotional appeals, many coming by mail from obscure institutions and faraway places, we are besieged to contribute to every conceivable area of good will and human need.

Americans have a reputation for generous giving, for caring for their fellow men, but this also makes us vulnerable targets for fund campaigns, some of whose natures, purposes, and methods, are questionable. We find it virtually impossible to give to all of the worthy drives.

Because organized fund raising has become big business—money-wise it is the fourth largest industry in the nation—the average citizen wonders if he can depend on his judgment alone to determine the campaign merits. He knows that most campaigns are masterminded by skilled professionals, hired for their scientific know-how about how to open the purse strings. For better or worse, these professionals are a necessity in this modern age, and we all realize this. We know that the future of great humanitarian endeavors hinges on how successfully a campaign is put across.

There is a great overlapping of appeals for funds by various organizations. This is particularly true in the medical field where societies have been formed to establish research funds and to relieve sufferers in almost every conceivable disease. The comedian, George Gobel, recently remarked that it is getting now so that there are hardly any good diseases left. Would it be possible to consolidate all the money raised for research into one fund?

The disturbing problem is pointed out by the following finding in a report from the Campaign Review Council in the city of Duluth. There are thirty-four separate groups now seeking public support in Duluth to aid crippled children and adults. Some of these groups are covered by the Community Chest; most of the others conduct private fund-raising campaigns. Some of the thirty-four groups are concerned only with research; others with rehabilitation; still others with giving personal aid. All are worthy causes, but where does the average citizen draw the line?

As doctors, we are often asked whether the funds raised by the various organizations are well supervised and well spent. I'm sure that we can honestly say that in the great majority of instances, the money received is well spent. However, the very multiplicity of all these campaigns will eventually lead to a point of diminishing returns.

Wouldn't it be possible for each of us in our own communities to work toward some form of consolidation of these various fund drives? In Duluth, for example there is one large fund drive occurring in almost every month of the year, not to mention many of the rather questionable requests for funds that are received from organizations outside our state at or near the holiday season. It is my fear that the very multiplicity of these drives will be the factor that "kills the goose that lays the golden egg."

TAKING NOTES AT MEDICAL MEETINGS

We have been impressed recently, not only with the tremendous number of note-taking techniques employed at medical meetings, but with the startling revolution our own note-taking has undergone. There was the day when we went to medical meetings with much note-taking paraphernalia including at least two never-fail mechanical pencils, that always managed to fail, and against the failure of which we also carried a freshly filled fountain pen. (In reviewing some of our old notes, however, it appears that a pencil can fail and the writer not become aware of it, for some of our notes appear only as indentations in the paper—no lead, notes taken in the dark.)

Then there was a refinement in note-taking; the flashlight. This required that a flashlight be added to a pocket already bulging with writing gear. When the lecturer demanded that the lights be turned out so he could show his slide, the note-taker grasped the flashlight and its switch in the left hand, his pencil (we assume it is still functioning) in the right hand, and somewhere between elbows, left forearm, knees and anterior aspects of thighs, managed to grip the note-book—and proceeded to take notes. There was always something satisfying in writing prettily under these circumstances; many of our notes were prettier than what we do sitting à la Palmer method at a desk. But a super-refinement came. The combination pencil (or pen) and flashlight. This took the whole note-taking business out of the realms of technique and reduced it to a semi-automatic mechanical process. It left too much time to think about the subject matter and has led directly to the degeneration of our note-taking. Degenerate it did from here on.

As soon as our mind was occupied only with what the lecturer was saying and doing, and the mechanics of note-taking no longer provoked the invigorating thrill of masterly exercise of a technical skill, we found our notes going along well for a line or so, then the words became more scrawly; finally, the words trailed to the vanishing point and were nothing, absolutely nothing. This was not as unsettling as it sounds, for we soon developed a lethargic, contented sort of satisfaction in the technique of dozing in a well-illuminated room without the lecturer or neighbors giving overt evidence of being aware of our sleeping. True, once in a while our technique slipped, and a neighbor was constrained to nudge an interruption to what he would later allege was noisy respiration, but, in a general way, we continued to bask in the self-satisfaction that comes from attending lots of medical meetings, *der ewige Student* type of reputation. Note-taking in itself, you see, had become as effortless as we'd like to have everything else in this life.

Disquieting news reaches our ears now, though. We've been told about people who go to meetings, take notes, rush to their hotel rooms, and transcribe the notes immediately! Now these folks are going to get ahead of us. They will have not only the reputation of going to great numbers of medical meetings, but will be insufferable enough to bring around their well-written notes, and, what's worse, be able to interpret them. This blow has been softened by the underground intelligence that slow decay is tanglefooting the adherents of this school. They have taken to transcribing their notes to the accompaniment of a long, cool drink—after a hot, tiring day in the lecture hall, you know—and the net result is reported to be like that in the system we have; i.e., first line or two is wonderfully written and then the words gradually become as blurred as the thoughts they express.

The other source of disquiet is in line with the reports of the colleagues who take portable dictating machines in their automobiles and dictate patients' histories while en route to or from house calls, weekends, and such like; or the folks who have machines to read tape-recorded medical literature to them while they drive. Insofar as note-taking goes, this type of efficient perfectionist rents a dictating machine at the meeting place, takes notes, rushes to hotel room, transcribes notes onto recording disc or belt, mails record home to his secretary, and has the TYPED notes waiting on his desk when he gets back. This is nothing if it isn't unsporting and, though we are terribly, terribly hurt by this win-regardless-of-cost attitude, we shall simply ignore this school of note-taking.

This brings us back to the good old method requiring no special equipment, available to all of us from the lowest type of specialist to the highest type of provincial physician, namely, alternate dozing and note-taking with a blunt stub of a pencil on the back of a tattered envelope. It gives you just as much satisfaction as any other method, takes just as much know-how, and will be read and referred to just as often and with equal yield as any flossier technique. And what's more, it gives time to observe that alert gent in the front row who listens eagerly, whose eyes fairly glitter with the joy of the game, and who gets up after the talk and, with obvious enjoyment, intelligently punches holes in the lecture and the lecturer.

H.G.M.

THE VALUE OF SPECIALTY BOARDS

With the unprecedented growth of medical science in the twentieth century came the pressing need for specialization to encompass newer and more refined developments in practice. Traditionally, Vienna and Berlin became the mecca for hordes of American physicians seeking postgraduate training. While many of these men were soundly grounded and motivated, the lack of standards and of measured attainment led to a sense of insecurity in the total program. Too frequently the sole evidence of special training was a series of patently meretricious certificates in the physician's office.

American medicine became increasingly aware of the necessity of keeping its house clean. As in other respects of public welfare, recourse to moral suasion rather than legal action was sought. The movement for the regularization of specialty training was initiated in 1916 by the foundation of the American Board for Ophthalmic Examination. Its terms of limitation were expressed as follows: "Each certificate granted or issued does not of itself confer or purport to confer upon any person any degree or legal qualifications, privileges or license to practice ophthalmology. Nor does the Board intend in any way to interfere with or limit the professional activities of any duly licensed physician." In the intervening years, eighteen additional specialty boards have been established, and, as in the case of the American Board of Ophthalmology (revised designation), recurrent expressions of the designs in the certification of specialists have been made. For example, the American Board of Surgery stated, "The prime object of the Board is to pass judgment on the education and training of broadly competent and responsible surgeons, not who shall or shall not perform surgical operations. The Board especially disclaims interest in or recognition of differential emoluments that may be based upon certification."

The Advisory Board for Medical Specialties, established in 1934, has co-operated with the Council on Medical Education and Hospitals of the American Medical Association in guiding the foundation of new boards and in establishing broad, general principles of procedure. However, the individual requirements of the several Boards have been derived without external influence. For example, in the early operation of the American Board of Internal Medicine, the conventional formula for admission to the examination was three years of residency and two years of the practice of internal medicine after graduation from a Class A medical school and one year of internship. After a period of years, the experience of the Board dictated a much more liberal policy, so that currently it is possible for a candidate to be admitted to this examination under one of several plans of preparation. Indeed, twelve years of the practice of internal medicine after the internship without a formal residency is considered a sufficient discipline. The ability of the candidate rather than the strictures of arbitrary terms of sharply defined service establishes his eligibility for certification.

By common consent, the specialty boards have contributed immeasurably to the improvement of the quality of medical service. The standards of specialty training in this country have improved apace as was anticipated when the several Boards were established. In a period when continental medicine deteriorated to an all-time low, the curve of medical education in this country showed an up-swing. In a material degree, this advance can be directly or indirectly traced to the movement for certification in the specialties. With the available facilities, new incentives for professional advancement were afforded a greater number of physicians. Furthermore, direction was lent to graduate training where none had existed before the advent of this program.

An overlooked dividend of certification in the medical specialties is the requirement of basic qualifications for candidates in the sub-specialties. In an earlier day, the acquisition of a gastroscope and a short course in gastroscopy abroad sufficed to qualify a physician in gastroenterology. The purchase of an electrocardiographic apparatus was tantamount to recognition as a cardiologist. Now such candidates must prove their adequacy in internal medicine before they can be admitted to the examination in the medical sub-specialty. By this simple expedient, the standards in the medical sub-specialties have been immeasurably advanced. Never has the American public been so well protected in the insurance of the qualifications of the practitioners in the various specialties of medicine and surgery.

Unfortunately, certification in medicine and surgery has not been an unalloyed blessing. Perhaps its greatest drawback has been the curious psychologic reaction of "working for the Boards." Perchance this response of immature minds is inevitable. Specialty boards set minimal standards of professional adequacy. Any interference with the continuing education and sustained growth of physicians must be met by positive measures. Unfortunately, the yardstick of certification is applied to the appointment and advancement of physicians in various capacities. The most pernicious device in its utilization has been its requirement by certain hospitals for staff appointment in spite of the expressed design of the several specialty boards. Conversely, the lack of certification has been used as a lever to deny staff appointments or to remove proved clinicians from established posts. Such abuses of the medium of certification are as unfair as they are reprehensible. Perhaps the leveling influence of time and experience is required in all good works.

The principle of supply and demand will unquestionably dictate changes in the programs of specialty training. Certification is a means to the end and not the end itself. The mechanism for rating the qualifications of specialists will vary widely among the several branches of medicine and surgery. Any formula that improves the quality of medical service should be encouraged; but the worthy efforts to broaden the base of training and to encourage the continued growth of specialists must not be submerged by the specious and hollow objective of mere certification.

William S. Middleton, M.D.
Dean of the Medical School
University of Wisconsin, Madison, Wisconsin

CHILD PSYCHIATRY

The rapidly growing field of social psychiatry has developed largely from the application of psychoanalytic theory to general behavior. This has changed considerably the nature of psychiatric practice. The psychiatrist, with few exceptions, no longer limits his work to the treatment of the more serious disturbances such as psychosis and psychoneurosis. He plays a more active rôle in the treatment of the many social and emotional maladjustments to life, and these include the broad fields of marital adjustment, delinquency, psychosomatic illness, and the art of living.

Research in the field of human behavior has demonstrated that the way a person feels, believes and behaves in adult life is largely conditioned by the early emotional experiences to which he was subjected. This has placed tremendous importance on the early years of life and has provided a large body of facts concerning the early development of personality.

There has been considerable research recently on the first few months of the infant's life, growing out of the observation that emotional pathology in the young child is due to the absence of a strong positive emotional tie between the infant and his mother. We are beginning to understand early childhood psychosis much better since this research began and we are rapidly developing a treatment program to deal with this condition. The facts gathered from this research have already been extended to other emotional problems of early childhood which are becoming more clearly understood for the first time.

Studies of children, as revealed through child guidance clinic work, demonstrate that children of all ages develop emotional pathologic conditions when there is something wrong in the relationship between them and their parents.

Rarely does one see a child who presents emotional pathologic conditions of any nature—whether it be night terrors, soiling, school failure, inability to get along with other children, hostile aggression, or delinquency—where the emotional relationship between the child and his parents is a healthy one. Almost invariably there is conflict between the parents, growing out of incompatibility, disloyalty, or the many other forms of family pathologic situations.

As a result, in order to effectively treat the emotional conflict or illness of the child, one must work intensively with the parent-child relationship, the problems in the parents themselves, and any problems created within the family. The best way to deal effectively with these problems is for the so-called team of social worker, clinical psychologist and psychiatrist to work together intensively with the child and his parents and all the many emotionally charged situations to which the child is subjected. This task can seldom be accomplished by the child psychiatrist alone; it is too complex and requires the skills of the several disciplines.

Recently, group therapy has been added to the psychiatric treatment of the child and we have found this to be an invaluable aid in the understanding of a child as he relates himself to other children.

The body of information required to carry on psychotherapy of children intelligently is so extensive, and the particular skills in understanding and helping a child are so important that a long period of intensive training is absolutely essential before a psychiatrist is prepared to do psychiatric treatment work with children.

ANNUAL MEETING

The 102nd annual meeting of the Minnesota State Medical Association will be held in Minneapolis, May 23-25, at the time of the 100th anniversary of the Hennepin County Medical Society.

Business sessions of the Council and House of Delegates will precede the scientific sessions which will begin Monday with meetings in the Minneapolis Auditorium. A tentative program will appear in the April number of Minnesota Medicine, and the official program should reach members about May 1.

THE VALUE OF A SAFETY DEPOSIT BOX

Century after century, down through the ages, the primary concern of man, after providing a livelihood for himself and his family, has been the protection of the surplus wealth accumulated as a result of his labor. Closely paralleling the development of the family unit into an organized society, the protection of the concentrated money of the community has been the responsibility of the banker. With this responsibility arose the problem of creating a depository which would safeguard the money and valuables entrusted to his care.

Ingenious, yet crude were the early methods employed, but from these humble beginnings evolved the modern steel vault, equipped with protective devices and guarded by massive doors weighing many tons, which today make the vault a marvel of safety and convenience, storm-proof, burglar-proof and fire-proof—safe against almost any act of nature or man.

The modern bank, by popular demand, has incorporated in its security function a deposit section containing thousands of safe deposit boxes in varying sizes which are available to the general public. It is not difficult to conceive the value of a safe deposit box for private use when it is realized that the legal evidence of much that mankind possesses, is on paper—paper which if lost, stolen or destroyed, might be impossible to replace. Insurance will help rebuild a home, purchase a new car, furniture or clothing after a catastrophe, but there are many items of intrinsic or sentimental value together with irreplaceable papers and documents which money can never restore.

The use of the safe deposit box is limited only by the imagination of the holder; it is not only a convenience but a means of protection also frequently utilized as an important tool in managing financial affairs in a systematic manner. It is peace-of-mind insurance for the individual, partnership or corporation—one of the most important yet comparatively inexpensive banking services offered.

UNDERGRADUATE EDUCATION FOR GENERAL PRACTICE

The trend toward specialization in medicine has been discussed with increasing frequency in recent years, and more often than not it has been deplored. Yet medicine's growing complexity suggests that this trend will not be reversed. On the other hand, the well-trained general practitioner will continue to play a vital role in the care of the sick. There can never be an acceptable substitute for the close personal relationship between a patient and his "family doctor."

The principal objective of a medical school is to provide its students with the basic tools essential for general practice. The same tools are equally necessary for the future specialist, teacher, or investigator. To the end of providing their students with a better background for medical practice, a number of schools have recently introduced changes in their curricula, for example, "integrated" teaching, family care plans, preceptorships. Although differing in their forms, each of these programs represents an attempt to give the student a broad view of medicine rather than a series of compartmentalized peeks.

Tradition and the appreciation of socio-economic realities allow us but four years for the formal education of a physician—a period unchanged in more than four decades. Yet today's student must assimilate an infinitely greater amount of information than did the student of 1915, considerably greater even than did the student of 1940. Two closely related conclusions may be drawn from this. First, medical students must be made aware that their education is, in fact, a life-long process and that their years in medical school represent only its beginning; and second, medical schools must plan their curricula with this in mind.

In light of an ever-expanding body of medical knowledge and a fixed period for formal undergraduate training, how may a medical school make best use of the four years during which its faculty is responsible for the education of its students? In our opinion, it must see that before graduation its students acquire the following:

1. A comprehensive knowledge of the basic medical sciences. If a student fails to acquire a real understanding of the basic sciences in medical school, it is most unlikely that he will do so after graduation.

2. The fundamentals of clinical practice in each of the various fields. This means that the student must be taught primarily the approach that is required in solving clinical problems.

3. An appreciation of the role of research in the continuing growth of medicine.

4. A knowledge of how to use medical literature effectively and, along with this, the background and attitude necessary for the critical evaluation of reports of new fundamental, diagnostic, and therapeutic developments.

5. An appreciation of the absolute necessity for integrity and adherence to the ethical code in the practice of medicine and a realization that the physician must accept civic and social responsibilities apart from his professional responsibilities.

6. An awareness of the various paramedical agencies, for example, public health, social service, occupational therapy, which can help him in rendering maximum service to his patients.

If we accept the foregoing as reasonable objectives for the medical school, two corollaries follows: (1) The general caliber of the internship, as an integral part of medical education, must be improved; and (2) The practicing physician will have to make increasing use of the various forms of continuing medical education.

In summary, the best undergraduate teaching program is one which will furnish the student a sound foundation on which he may base his future training. His personal preferences and interests may take him into general practice, specialty practice, teaching and research, public health, or administration. Regardless of his later choice, such a background will make him a better physician.

George Earl, M.D., Chairman

HEALTH MESSAGE SHOWS LITTLE CHANGE

President Eisenhower's health message to the Congress carried no recommendations that had not been made earlier in his State of the Union or budget messages, except his request for a bigger U. S. contribution to World Health Organization. The AMA congratulated the President on his statement that health proposals "recognize the primacy of local and state responsibility" and would "encourage private efforts with private funds."

His comments and basic outlines for health programs are:

Reinsurance.—The Administration wants Congress to appropriate $25 million to start a federal reinsurance fund for the use of voluntary health insurance groups. The President said reinsurance would be most helpful in three broad areas (a) with rural families, (b) to expand catastrophic insurance, and (c) to bring protection to low-income families in the form of coverage for home and office calls as well as hospitalization. Last year the House defeated a reinsurance bill that followed the same lines but that did not pinpoint certain areas. This was introduced in the omnibus health bill S. 886.

The AMA's official comment on this proposal was that the AMA has been in complete accord with the stated purpose of legislation designed to promote voluntary health insurance and commended the President for his beliefs and efforts in encouraging its expansion. However, the AMA still believes that the proposed reinsurance system will not achieve the desired results.

Medical Care for Indigents.—The President described the present medical care program for public assistance recipients as "far from adequate." He proposed $20 million more in U. S. appropriations, to be matched by the states and placed in a separate fund exclusively for medical care payments. This fiscal year the U. S. is spending about $80 million in this field. The AMA was not prepared to comment on this proposal yet.

Mortgage Guarantee.—The Administration is offering an amended version of last year's Kaiser-Wolverton bill for U. S. guarantee of private loans for health facilities. The President said: "Present methods of financing are not always satisfactory in meeting this problem. Many sponsors and operators are unable to qualify for grants under the recently extended hospital survey and construction act (Hill-Burton). Sponsors of health facilities often find it difficult to obtain private capital for construction." The AMA said it has no opinion yet on this measure.

Health Personnel.—Three methods are proposed to increase the supply of trained personnel, (a) grants to states for training practical nurses, (b) Public Health traineeships for graduate nurses in specialty nursing fields, and (c) establishment of PHS traineeships in public health specialties, including mental health. The AMA commended the President for his support of these proposals.

Mental Health.—Three approaches recommended (a) more aid to states and communities, (b) more money to train personnel for care of mental patients under present authorizations, (c) a new program of project grants aimed at improving the quality of care in institutions and searching out ways of reducing length of stays. The latter point is in recognition of the fact that the care of mental patients is the heaviest financial burden in the medical fields for most states. The AMA agreed with the President on this matter also.

Also included in the President's recommendations to Congress is the extension of the "Doctor-Draft" act. This is incorporated in H.R. 2886, which simply extends the act for two years.

PRESIDENT'S BUDGET IS EXTENSIVE, EXPENSIVE

The Administration has presented Congress its formal request for funds to maintain all programs, including health and medical, for the 1956 fiscal year starting July 1, 1955. The total request for the Department of Health, Education and Welfare is $2 billion, just a slight increase over the current year's estimated spending.

Included in this amount is the request for Hill-Burton hospital construction funds amounting to $125 million. This will be for new facilities and grants to complete hospitals now under construction.

Increased funds were also requested for research projects, some as much as 50 per cent.

VA Medical Care Costs

Medical care costs for the Veterans Administration were set at almost $889 million, compared with $862 million in current spending; hospital construction costs were set at $60 million (mostly remodeling) as compared to the current $50 million.

In his budget message the President expressed concern that the VA patient load would rise 4 per cent next year and that:

> ". . . more than two-thirds of the expenditures will still be for patients hospitalized or treated for ailments not connected with military service. . . . we must bear in mind that government policies designed to assist in the maintenance of a prosperous economy and to support social security, health, and other humanitarian programs are all of value to veterans as well as to other people. Since more than two-fifths of all adult males are entitled to veterans' benefits, expenditures for veterans are a budgetary problem of major interest to the whole population."

STANDARD HEALTH INSURANCE PLAN PROPOSED FOR U.S. WORKERS

The Administration has revised its plan for health insurance for federal employes and is proposing a three-way option for them: participating in (1) a new standard, nationwide plan, (2) existing plans sponsored by their own national employe organizations, or (3) local plans offered in their community or through local employe unions or other agencies.

The standard plan would offer catastrophic or major medical care insurance. It provides:

1. U. S. estimated contribution would be $55 million a year, paying up to one-third of premium costs, with a limit of $1.50 per month for employes without dependents and $4 per month for those with dependents. If the employe chooses the standard national coverage, the cost to him would be $3 per month if he has no dependents and $8 per month if he has dependents. On other types of coverage, the employe's payments would vary with the premiums, but U. S. contribution would still not exceed the above figures.

2. The standard plan would be straight cash indemnity based on a schedule of benefits set by the Civil Service Commission.

3. Major medical cost protection would be restricted. After the policyholder had exhausted the benefits of the basic policy, he would have to meet the next $100 of expenses himself. Then, the standard policy would reimburse him for 75 per cent of the costs up to a maximum of $2,500.

4. After a minimum of fifteen years' civilian service, employes who retire would be permitted to continue under the program by authorizing premium deductions from their retirement checks.

5. Civil Service Commission would be responsible for administration of the entire program, but would contract with a single insurance company to operate the national standard plan. It would not become operable, however, unless 600,000 of the 1,800,000 eligible government workers agree to participate.

COMPULSORY HEALTH INSURANCE AGAIN INTRODUCED

H.R. 95 is a verbatim copy of H. R. 1817 introduced in the 83rd Congress two years ago, providing, among other things, for national compulsory prepaid personal health insurance. Its author is Rep. Dingell of Michigan, author of the previous bill also. It also provides for subsidies for federal aid to medical education, medical research, hospital construction act amendments, special aid for rural and other shortage areas, state grants for local public health units, research in child life and additional grants for maternal and child health and crippled children's services.

M.D. SHORTAGE IS A FADING SPECTER

A recent editorial in *Medical Economics,* the monthly magazine, notes the rapid rise in the number of medical schools in the nation, to help refute the idea that there is an acute doctor shortage in America.

The editorial stated: "For years there's been agitated debate about a national doctor shortage. Medical men couldn't stop it by pointing to the increasing size of graduating classes pouring forth from existing medical schools."

Reasons given were that the population was increasing just as fast. For, between 1940 and 1950 the total number of physicians in this country increased by 15 per cent; but the total population increased 15 per cent too.

But, the editorial notes what is happening today: Two new medical schools (the University of North Carolina and the University of Puerto Rico) produced their first graduating classes within the past year. Eight more new schools (U.C.L.A., Albert Einstein, Seton Hall, and the universities of Miami, Missouri, Mississippi, West Virginia, and Florida) are ready for early training of doctors.

The editorial quotes statisticians as believing then "the rise in the number of medical graduates should be relatively more rapid than general population increases in the course of the next six to ten years."

In conclusion, the *Medical Economics* editorial says:

> "This heartening break-through doesn't solve *all* our doctor-supply problems. There's an unquestioned shortage in certain local areas and in certain key specialties. But at least the specter of a *national* doctor shortage should begin to fade."

BUSINESS HAS AN INTEREST IN HEALTH

According to Benson Ford, president of the Board of Trustees of Detroit's 650-bed Henry Ford Hospital, business has a substantial interest in health and health problems throughout America. Mr. Ford is also vice president of the Lincoln-Mercury division of Ford Motor company.

In a speech at the 56th annual convention of the American Hospital Association, quoted in the December, 1954 issue of *Hospitals,* Mr. Ford said that "of the 43 million Americans who take part in Blue Cross, a large majority are covered by industrial group plans. Industry also foots part of the bill for millions more Americans in other insurance plans. Add to that the cost of private industrial medicine, insurance against industrial accidents and illness, and it becomes clear that business has a substantial interest in the whole health system of our country.

Mr. Ford outlined the broader problem of union demands on industry, the aging population and other problems which affect industry's interest in health matters. But he stated:

> "Up to this point, I seem to have painted a picture of a pretty sadly-confused health situation. That would hardly be a true or fair picture. Most of our present difficulties are inherent in the nature of the private enterprise system. Ironically, it is the very high quality of our private medicine and our partial success in developing private means of financing medical care that make it possible for us to enjoy some of these worries I've been talking about."

Suggests Permanent Health Commission

Mr. Ford suggested a solution to the national problems of health matters in a health commission representing all the major segments of the health profession, to examine our major health needs and to recommend how best these needs can be met.

"I'm not suggesting a super-lobby to fight socialized medicine or a 'politburo' to dictate hospital and medical practices," Mr. Ford continued. "I have in mind a top-level professional group adequately staffed to study the developing pattern of wants and demands and to establish standards and practices for the guidance of all our services, including hospitals, clinics, medical schools and medical research centers."

In conclusion, he said, "I think we must all recognize the existence of a broad public desire for a kind of health care commensurate with the vast wealth and resources of our nation." He declared:

> "If you, the professionals of health, can supply the drive and leadership to get that job under way, I am sure you will win the earnest gratitude and also the eager co-operation of industry, of labor, of government and of all the American people in helping you solve a great public problem by private action."

Public Health

DUTIES OF THE PHYSICIAN IN REGISTERING BIRTHS AND DEATHS

The physician is the first person to take official note of a birth or a death. On him, therefore, rests the responsibility for prompt and accurate reporting of these events occurring in his practice. Laws regarding the reporting of vital events are changed from time to time. For the help and guidance of physicians, the Minnesota State Board of Health herewith presents the current requirements.

The Vital Statistics law requires the physician to:

(a) File a birth certificate for every live birth he attends.

(b) Certify the cause of death when he is the physician last in attendance, unless the case is under coroner's jurisdiction.

Birth Certificates.—The Vital Statistics law requires the attending physician to file, within five days, with the local registrar of the district where birth occurs, a birth certificate for every live-born infant he has attended.

Exception.—A birth certificate for a child *born out of wedlock must be filed directly and promptly with the state registrar,* 469 State Office Building, St. Paul 1, Minnesota. (Local registrars are clerks of the District Court, except in cities which by ordinance maintain a primary registration district. In such cities, of which there are twenty-two in Minnesota at present, the health officer is the local registrar.)

Reportable Births.—Live births and stillbirths are reportable after twenty weeks' gestation.

Live Births.—The standard definition of a live birth is "an infant which either breathes or demonstrates heart beat or movement of voluntary muscle after it is completely outside the body of the mother." Live births are to be reported on the *Live Birth* certificate; stillbirths on the *Stillbirth* certificate.

Hospital Births.—A birth record is a legal record and is of great importance to the person throughout his life. When hospital personnel prepare birth records for the physician, he is nevertheless responsible for their legibility, completeness, and verity. He must sign them in his own handwriting. They must also be dated. If the physician is not satisfied with their appearance or content, he should require that they be made out again before he signs them.

Stillbirths.—If a funeral director takes charge of the body of a stillborn infant, the law requires him to prepare a certificate and to present it to the physician for certification of the causes indicated. If there is no funeral director, the hospital or the physician may take the initiative in preparation of the certificate.

Death Certificates.—The funeral director is required to present the death certificate to the physician last in attendance, for certification of the cause of death, unless the coroner has jurisdiction, in which event the certificate must be presented to the coroner. Physicians and coroners should promptly certify the cause of death and immediately thereafter return the certificate to the funeral director so that he can file it and obtain the required permits before burial or other disposition of the body.

Cause of Death.—Cause of death should be certified in full (abbreviations should not be used) according to directions set forth in the World Health Bulletin, Medical Certification of Cause of Death, obtainable from the Section of Vital Statistics, Minnesota Department of Health, 469 State Office Building, St. Paul 1.

Autopsy Pending or Diagnosis Deferred.—If autopsy is pending or diagnosis is deferred for some other reason, the physician or coroner should so state in the death certificate. He should date and sign the certificate and return it at once to the funeral director. At a later date, the state registrar will obtain a statement of the cause of death from the physician or the coroner.

It may be of interest to physicians to know that Minnesota rated 99.9 per cent completeness in the registration of births in the 1950 birth registration test conducted by the Bureau of the Census in co-operation with the National Office of Vital Statistics and the Vital Registration Executives of the United States. Minnesota was tied with Rhode Island for second place among the states, exceeded only by Connecticut with a rating of 100 per cent. Credit for this achievement was due to the physicians, hospital personnel, and local registrars of Minnesota who have most faithfully fulfilled their legal obligations regarding birth registrations. During the test period studied, only two Minnesota physicians failed to report. Constant co-operation between local and state officials is necessary if the high standard of vital reporting in this state is to be maintained.

Director, Division of Departmental Administration
Minnesota Department of Health

Current Concepts

DIET AND ATHEROSCLEROSIS

ANCEL KEYS, Ph.D.
Minneapolis, Minnesota

The theory that the diet may affect the development of coronary heart disease is not new. For years, the balance between pro and con teetered under the accumulation of indecisive evidence from animal experiments, often having little relevance to the real problem in man. Recently. however, the increasing dominance of coronary heart disease in our national health picture has stimulated much more research, and some of this has been more systematic and more directly concentrated on man himself. The result is that we can now see some of the outlines, if not the details, of a major relationship between the habitual diet and the tendency towards atherosclerosis and resultant coronary heart disease.

Perhaps the most crucial evidence is that human populations who subsist on different diets show great differences in the prevalence of clinical coronary heart disease, in the age-specific mortality ascribed to coronary or degenerative heart disease, and in the incidence of atherosclerosis seen at autopsy. The old impression that coronary heart disease may be rare in some populations, such as the Chinese, has been replaced with conclusive data. It is now clear, for example, that middle-aged men in the United States have perhaps ten times as much atherosclerosis, and die far more frequently from coronary heart disease, than do South African Bantu, or Japanese of the same age. It is not simply that white men are more afflicted than men of the Mongol or Negroid races, because there are also notable differences between white men. We may contrast Minnesotans with Italians or Spaniards, for example, and point to differences between white men in the same country, such as rich versus poor Spaniards, or Italians in Naples versus Italians in Bologna. It is most significant that the indicated differences between populations in regard to coronary heart disease appear to be parallel to differences in the average concentration of cholesterol in the serum in samples of these populations.

The unifying concept that brings order into an otherwise mystifying picture is that the proportion of fat in the diet has a powerful effect on the serum cholesterol level and so on the development of atherosclerosis. The dietary cholesterol itself is unimportant, but whether different neutral fats in the diet have different effects is as yet undecided. The important point is that all of the data —and they come from Guatemala, Sweden, and England as well as from Spain, Italy, South Africa, Japan and the United States—show a remarkably regular and direct relationship between the total fat content of the diet and the prevalence of coronary heart disease at given age. Further, the experiences of World War II and after, when many countries changed their diets, are in close agreement and indicate that dietary changes may have large effects on mortality in populations in a year or so.

It is significant, then, to note that our average American diet is the world's highest in fat and that the proportion of our dietary calories supplied from fats has been steadily increasing for a long time. Contrast our present more than 40 per cent of calories from fats with the 20 per cent figure for the Neopolitan or the 8 per cent figure for the Japanese!

As yet, there is little evidence that dietary manipulation will greatly change the prognosis of the coronary patient, though time may change this picture, but it is already reasonable to hope for real progress towards prevention through dietary means. Obviously, we need much more research. particularly systematic studies on populations which can tell us things not to be learned from our laboratory animals, but the future ahead looks bright. We can now be sure that age alone does not inevitably bring atherosclerosis and coronary heart disease.

It is clearly evident that our public health problems of the future will be concentrated among older persons, among whom chronic disease and disability are more prevalent; their social and economic overtones will have an impact on almost every family. Our plans must encompass the degenerative diseases, the long-term illnesses, and the disabling conditions of older age groups. This does not mean that we can relax our guard against communicable diseases, nor lessen our campaign to reduce infant and maternal mortality, nor let up on our crusade to eradicate tuberculosis. Environmental sanitation is as important as ever and requires constant vigilance to keep the air, water, food, and milk free from pollutants including those spawned by atomic fission. Herman E. Hilleboe, M.D., *New York State Journal of Medicine,* December, 1954.

Reports and Announcements

MEDICAL MEETINGS

State

MINNESOTA STATE MEDICAL ASSOCIATION, annual meeting, Minneapolis, May 23-25, 1955.

National

American Association of Blood Banks, eighth annual meeting, Palmer House, Chicago, Illinois, November 19-21, 1955.

American Cancer Society, Board of Directors and special committee meetings, Hotel Radisson, Minneapolis, June 2, 1955.

Inter-American Congress of Radiology, Shoreham Hotel, Washington, D. C., April 24-29, 1955.

International Hospital Congress, Lucerne, Switzerland, May 30-June 3, 1955.

INTERNATIONAL COLLEGE OF SURGEONS

The United States and Canadian sections of the International College of Surgeons, through the generosity of the Women's Auxiliary, are offering two opportunities to young Canadian or American surgeons.

One is a scholarship of $3,000 to pay for transportation and living expenses for one year for a young surgeon who wishes to study abroad. The doctor selected for the scholarship will be expected to spend at least ten months of the year as a resident or fellow in a teaching center in Europe or South America.

The other is an invitation to two residents or fellows in training in surgery to attend the annual meeting of the college and present a clinical or scientific paper. Transportation and living expenses during the meeting, not to exceed $300, will be provided by the college. The next annual meeting will be in Philadelphia from September 12 through September 15.

Further information concerning both offers can be obtained from the Scholarship Committee, International College of Surgeons, 1516 Lake Shore Drive, Chicago, Illinois.

AMERICAN INSTITUTE OF DENTAL MEDICINE

The next annual meeting of the American Institute of Dental Medicine will take place at the Desert Inn, Palm Springs, California, October 23 to 27. The faculty will consist of Maury Massler, D.D.S., M.S., University of Illinois, Chicago; Valy Menkin, M.D., Temple University Medical School, Philadelphia; Hans Selye, M.D., University of Montreal, Canada; Reidar F. Sognnaes, D.M.D., Ph.D., Harvard School of Dental Medicine, Boston; Wendell L. Wylie, D.D.S., University of California, San Francisco.

All seminar lecturers will participate in a round table forum discussing the application of their subject to the practice of dental medicine. Applications and full information may be secured from the executive secretary, Marion G. Lewis, 2240 Channing Way, Berkeley 4, California.

COURSE IN CLINICAL PATHOLOGY AND PATHOLOGY OF PARASITIC DISEASES

A short, intensive course on the laboratory diagnosis and pathology of parasitic infections will be presented August 15-27 at the Louisiana State University School of Medicine in New Orleans.

The course is designed primarily for pathologists and technologists. However, general practitioners, internists, pediatricians, gastroenterologists and physicians engaged in the practice of public health and tropical medicine who are interested in the laboratory diagnosis of parasitic infections are welcome to attend. The instruction and training will be of assistance to pathologists who are preparing for board examinations, to pathologists and physicians who are responsible for the diagnosis of parasitic infections in their laboratories and to technologists engaged in this specialty.

Registrants should bring their microscopes, equipped with mechanical stages, and their microscope lamps. A limited number of places will be available. The fee for the course is $50.

Persons interested in attending this course may write to: Dr. Clyde Swartzwelder, Department of Microbiology, Louisiana State University School of Medicine, 1542 Tulane Avenue, New Orleans 12, Louisiana.

PAN AMERICAN MEDICAL ASSOCIATION

The next and tenth Inter-American Congress of the Pan American Medical Association will be held in Mexico City. The scientific sessions will begin on March 25, 1957. The Congress will be held in sections covering all branches of medicine and surgery. There will be medical moving pictures, panel discussions and scientific and technical exhibits. The association has forty-two medical sections including the new Section of General Practice.

Four days will be devoted to scientific sessions, and the next three days will be spent in sight-seeing, with visits to Cuernavaca, Taxco and Acapulco. The following week medical meetings will be held in Guatemala City in conjunction with the local chapter there.

The president of the Association is Dr. Pedro A. Gutiérrez Alfaro, Minister of Sanitation and Public Welfare of Venezuela, and the executive director is Dr. Joseph J. Eller, 745 Fifth Avenue, New York, New York.

SURVEY OF POSTGRADUATE MEDICAL EDUCATION

The Council on Medical Education and Hospitals of the American Medical Association has completed a comprehensive survey of postgraduate medical education in the United States. The material collected during the study has been worked into a final report and is being published as a series of special articles in the *Journal of the American Medical Association*. The first study titled "The Scope and Extent of Postgraduate Medical Education in the United States," was published in the February 26 number. Others will appear as follows: March 12, "The Physician as a Lifelong Student. March 26, "The Objectives and Content of Postgraduate Medical Education." April 9, "Educational Methods in Postgraduate Teaching." April 23, "Time and Place Arrangements of Postgraduate Courses for Practicing Physicians." May 7, "Sponsorship and Administration of Postgraduate Medical Education." May 21, "Financing Postgraduate Medical Education." June 4, "The Future of Postgraduate Medical Education."

ART AND HOBBY SHOW AT STATE MEETING

An exhibit of art and hobby projects is to be shown at the Minnesota State Medical Association annual meeting, scheduled for Minneapolis on May 23, 24 and 25. The exhibition will be more inclusive than ever before; not only paintings in various media, photography and sculpture are being shown, but also any hobby projects which are suitable for this type of exhibit. Complete information and entry blanks will be available in April from the State Office, 496 Lowry Medical Arts Building, St. Paul. Any Minnesota doctors doing any of the above type of art or hobby work are encouraged to exhibit. The showing will be appraised by competent judges, and numerous awards will be given. Co-chairmen for this event are Dr. J. S. Milton and Dr. F. A. Zinter, Minneapolis.

PUBLIC HEALTH RADIO-TV SERIES

A thirteen-week series of programs on public health will be presented on stations KSTP and KSTP-TV, Twin Cities, beginning March 9. The programs, which will consist of interviews of public health officials by Bee Baxter, radio and television personality, have been planned in co-operation with the section of public health education of the Minnesota Department of Health.

The interviews will be carried on television (KSTP-TV) on Wednesdays at 1:30 p.m. and on KSTP radio on Thursdays at 11:30 a.m.

Persons to be interviewed on the series include Dr. R. N. Barr, Dr. Helen Knudsen, Dr. Henry Bauer, Dr. Dean S. Fleming, Alberta Wilson, Dorothy Hagland, Dr. A. J. Chesley, Dr. Carl Lundeberg, Dr. A. B. Rosenfield, Frank L. Woodward, Herbert Bosch, Dr. Dale C. Cameron, Marie Ford and Dr. Gaylord Anderson.

MINNESOTA HEART ASSOCIATION

Minnesota institutions and individuals desiring consideration of Grants-in-aid and Fellowships in support of cardiac research and study from the 1955-56 research budget of the Minnesota Heart Association must present their requests on or before May 1, 1955.

Approved grants will extend from July 1, 1955, through June 30, 1956.

Further information may be secured by writing the Minnesota Heart Association, 532 Endicott on Fourth, Saint Paul 1, Minnesota.

THE MINNESOTA STATE BOARD OF MEDICAL EXAMINERS

F. H. Magney, M.D., Secretary

License of Arthur F. Sether, M.D., Suspended for Three Years

On February 4, 1955, the Minnesota State Board of Medical Examiners suspended for a period of three years the medical license held by Arthur F. Sether, M.D., of Ruthton, Minnesota, because of his violation of the terms of a stipulation which Dr. Sether signed following his personal appearance before the Board on May 18, 1951, in response to a citation for the revocation of his license. In that stipulation, which Dr. Sether entered into with the Board on August 23, 1951, in addition to other provisions he agreed to refrain from the personal use of the so-called barbiturates and alcoholic liquors in every form. It was because of the violation by Dr. Sether of this portion of his agreement with the Board that his medical license was suspended.

Dr. Sether, who was licensed to practice medicine in Minnesota in 1935, was born in St. Paul, Minnesota, on November 5, 1905. After taking a one-year internship at Minneapolis General Hospital, Dr. Sether graduated from the University of Minnesota with an M.D. degree in 1936. In the following year Dr. Sether opened an office for the practice of medicine at Ruthton, where he has practiced since that time.

Woman's Auxiliary

MID-WINTER MEETING WELL ATTENDED

Mrs. L. Raymond Scherer

The Mid-Winter Board meeting of the Woman's Auxiliary to the Minnesota State Medical Association was well attended despite below-zero weather.

The meeting was held February 10 at the Town and Country Club in St. Paul and was attended by county and state auxiliary officers and committee chairmen.

Members were welcomed by the auxiliary president, Mrs. Peter S. Rudie of Duluth. This was followed by the pledge to the flag and the pledge to the auxiliary, led by Mrs. John Dordal of Sacred Heart.

Regular reports of the secretary and the treasurer were read and approved, followed by a report of the president on the meeting of presidents and presidents-elect in Chicago during November of 1954. Mrs. Rudie stated that the meeting offered an excellent chance for an exchange of information with other state auxiliary presidents, and she reported on the many excellent panel discussions, including such subjects as organization, program, publications, *Today's Health,* the American Medical Education Foundation, public relations, legislation, civil defense, mental health, allied medical careers, and finances.

Following Mrs. Rudie's report, members heard a report from the president-elect, Mrs. H. H. Fesler of St. Paul, and the second vice president, Mrs. V. J. Schwartz of Minneapolis. Then followed reports from regional advisors in attendance: Mrs. O. M. Heiberg of Worthington, Mrs. Ralph Creighton of Minneapolis, and Mrs. J. C. Buscher of St. Cloud who reported on activities of auxiliaries in their districts.

State committee chairmen reported on various activities of their committees; reports were heard on Bulletin, legislation, organization, program and health education, public relations, American Medical Education Foundation, health days, newsletter, school of instruction, medical and surgical relief.

County auxiliary presidents in attendance told of individual county auxiliary projects. Reports included were from presidents of the following county auxiliaries: Hennepin, Park Region, Ramsey, Renville-Redwood, St. Louis and Stearns-Benton.

Following the completion of the business meeting, auxiliary members attended the luncheon meeting, presided over by the president. Mrs. Rudie introduced Mrs. V. J. Schwartz, Minneapolis, second vice president, who in turn, introduced Miss Marguerite Breen, Director of Public Relations for the Minnesota Tuberculosis and Health Association. Miss Breen thanked the state auxiliary for its many years of participation in her organization's program of promoting tuberculosis essay contests among high school and junior high school students in Minnesota. She exhibited the annual plaque and trophy given to the best essay on tuberculosis by a junior and senior student each year. The auxiliary sponsors this project jointly with the tuberculosis and health group, and Mrs. Schwartz served as a judge for the 1954 awards. Miss Breen then presented Barbara Sitzman, senior division winner, and Judy Lewis, junior division winner, who presented their prize-winning essays. Both girls are from St. Agnes High School in St. Paul. Auxiliary members agreed that their essays were of excellent quality and fully deserving of the awards they won.

RAMSEY COUNTY AUXILIARY REPORTS ACTIVITIES

Mrs. L. T. Simons

The State Medical Auxiliary Mid-Winter Board meeting was held on February 10, 1955, at the Town and Country Club, St. Paul. Mrs. W. H. Von Der Weyer and Mrs. B. E. O'Reilly were in charge of hospitality. Ramsey county members present were: Mrs. W. P. Gardner, president, Mrs. H. O. Peterson, president-elect, Mrs. Charles Waas, Mrs. C. W. Froats, Mrs. J. L. Benepe, Mrs. H. H. Fesler, Mrs. Mark Ryan and Mrs. John Ryan. Mrs. P. K. Arzt, chairman of state and Ramsey county legislation, presented both her own report and Mrs. E. M. Hammes' concluding report on the Dr. William A. O'Brien fund.

The Auxiliary took part in the Inter Club Council's "What's Cooking?" program held in the Lowry Hotel on March 28, as its public relations project for the year. Mrs. J. F. Madden and Mrs. J. R. Meade, auxiliary representatives, organized the medical scholarship material used on the education panel. Dr. Charles Rea, St. Paul, a member of the panel, spoke on medical scholarships and their allied fields. Mrs. O. I. Sohlberg served in an advisory capacity on the planning of the legislation panel.

Mrs. R. O. Burmeister, philanthropic chairman, reported a total of 175 cancer dressings. The Auxiliary assists this committee by making dressings during and following the board meetings.

The Medical and Surgical Relief Committee, Mrs. H. F. Schroeckenstein, chairman, packed 29 cartons of supplies in January. These were sent to the Episcopal Mission Orphanage in Osaka, Japan.

Mrs. R. F. Sturley, nurse recruitment chairman, reported her committee has been busy arranging for transportation of nurses to Murray, Roosevelt and Mahtomedi High Schools during February. These nurses talk to junior and senior girls who are interested in nursing as a career.

In Memoriam

ALOYSIUS STEPHEN FLEMING

Dr. A. S. Fleming, formerly of Minneapolis, died January 19, 1955, at Madison, N. J., where he had been living since his retirement in 1950. He was eighty-three years old.

Dr. Fleming was born in Eau Claire, Wisconsin, in 1872. He attended the University of Wisconsin for two years and got his medical training at the medical college of Hamline University. For fourteen years, he practiced in Wheaton, Minnesota, before coming to Minneapolis in 1913.

He was a former member of the staff of Hillcrest Hospital and was a member of the Hennepin County Medical Society, the Minnesota State Medical Association, and the American Medical Association. He was also a "Fifty Club" member of the Minnesota State Medical Association.

Surving are three sons, Noel C., Madison, N. J.; Dr. Dean S., Hopkins, and Allan W., Duluth; a daughter, Helen Fleming, Madison, N. J., and four grandchildren.

CHARLES HARRY GHENT

Dr. C. Harry Ghent, St. Paul physician, died January 31, 1955, in St. John's Hospital, St. Paul. Dr. Ghent had been ill for four months. He was sixty-six.

Dr. Ghent was born in Centralia, Illinois, in 1888. He graduated from the Northwestern University Medical School in 1911 and interned at Passavant Hospital in Chicago. He practiced in Dawson, Minnesota, and White Rock, South Dakota, before moving to St. Paul in 1916.

He had been a member of the staff of St. John's Hospital since 1916 and was also on the staff of Mounds Park Hospital. He was a member of the Ramsey County Medical Society, the Minnesota State Medical Association and the American Medical Association.

Dr. Ghent is survived by his wife, Florence; a daughter, Mrs. John B. Rutledge of Chicopee, Massachusetts; a sister, Mrs. John B. Hamilton, Carbondale, Illinois; and three grandchildren.

CHARLES ALBERT HALLBERG

Dr. Charles A. Hallberg, Minneapolis physician and surgeon, died suddenly January 30, 1955, at St. Barnabas Hospital. He was sixty-seven.

Dr. Hallberg was born in Stockholm, South Dakota. He received his medical degree at the University of Illinois in 1911 and interned at University Hospital in Chicago.

In 1917, Dr. Hallberg went to the Mayo Clinic, Rochester, Minnesota, on a fellowship. Except for a period of service during World War I, he remained there until entering private practice. He became an associate in medicine on the Mayo Clinic staff and took his specialist training in surgery there. He entered private practice in Minneapolis in 1926.

A staff member of St. Barnabas and the Northwestern Hospitals, Dr. Hallberg was a fellow of the American College of Surgeons, a member of the American Medical Association, the Minnesota State Medical Association and the Hennepin County Medical Society and the Minneapolis Surgical Society.

He is survived by two sisters, Mrs. Alma Darud, Seattle, Washington, and Mrs. Amanda Oestrich, La Bolt, South Dakota.

RAY GEORGE JOHNSON

Dr. Ray G. Johnson, Stillwater physician, died January 14, 1955. He was fifty-nine years old.

Dr. Johnson was born in Waltham, Minnesota, in 1895. He obtained a B.S. degree from Carleton College in 1920 and his M.D. degree from the University of Minnesota Medical School in 1924.

Following his internship at Mounds Park Hospital in St. Paul, Dr. Johnson practiced in St. Paul until 1938. In 1939, he became resident physician at the Minnesota State Prison at Stillwater.

He was a member of the Washington County Medical Society, the Minnesota State Medical Association, the American Medical Association, St. John's lodge No. 1, and A. F. and A. M.

He is survived by his wife, Ida May; two daughters, Barbara and Janet Rae; one brother, Vaughn, of Terry, Montana; two sisters, Mrs. Howard Crowther, Saint Paul and Mrs. Mabel Jordre of Oberon, North Dakota.

GEORGE P. KIRK

Dr. George P. Kirk, physician of East Grand Forks, Minnesota, died on January 20, 1955, at the age of eighty-one.

Dr. Kirk was born in Minnesota in 1874. He graduated from the University of Minnesota Medical School in 1896.

In 1949 Dr. Kirk, a member of the Red River Valley District Medical Society, became a life member of the Minnesota State Medical Association. He had been a member of the State Association for forty years.

During his active life, Dr. Kirk had been a health officer and city doctor. He was on the staff of St. Michael's and Deaconess Hospitals.

Dr. Kirk is survived by his wife, Anna; two sons, Cyrus of Minneapolis and Paul of Edmonton, Alberta, Canada; one daughter, Mrs. Edward Kuppich of Fargo; a brother, John H. of Glendale, California; a sister, Mrs. Ernest Freivogle of Richfield, Connecticut; and seven grandchildren.

Of General Interest

On February 3, two hundred Winnebago citizens turned out to honor the forty-seven years of service of **Dr. M. D. Cooper.** Dr. and Mrs. Cooper were guests of honor at a testimonial dinner sponsored by the Winnebago Community Club in the Presbyterian Church.

"This Is Your Life" theme was carried out, with many citizens and friends giving short tributes to the doctor's contribution to the life and welfare of the community. **Dr. Ralph Armstrong,** president of the Blue Earth Valley Medical Society, commended Dr. Cooper's long years of service.

In accepting the many honors, Dr. Cooper pointed out that when he arrived in Winnebago it was a thriving town, that there were several industries, three hotels and a college. "However," he said, "it was not these things that brought me here. It was the people."

* * *

Dr. Philip S. Hench, Rochester, presented a talk entitled, "X Marks the Spot," at a program in St. Paul on February 17, sponsored by the Rochester Area, Women's Association, Minnesota Historical Society.

* * *

Principal speaker at a meeting for heart fund volunteers in Anoka on February 16 was **Dr. Morley Cohen,** Minneapolis, who spoke on "Recent Advances in Treatment of Heart Disease in Children."

* * *

Dr. R. H. Puumala, of Cloquet, attended a postgraduate course in internal medicine at the University of Minnesota Continuation Center in mid-February.

* * *

At the annual meeting of the Fosston Hospital Association in Fosston on February 8, **Dr. George Sather** gave a talk on different types of hospital and medical insurance policies.

* * *

It was reported early in February that the Westbrook Commercial Club was hoping to locate and persuade another physician to open a practice in or near Westbrook. The community now has one physician.

* * *

Dr. George S. Allen, Mineral Springs Sanatorium, Cannon Falls, attended the Veterans Administration Army-Navy Conference in Atlanta, Georgia, early in February. Subject of the conference was the chemotherapy of tuberculosis.

* * *

Dr. and Mrs. Edward D. Detjen, Bigfork, spent the first week of February in Texas, visiting relatives and absorbing sun.

* * *

Principal speaker at the annual meeting of the Citizens Mental Health Association at Minneapolis on February 18 was **Dr. Adelaide M. Johnson,** Rochester, who discussed problems of bringing up children in modern society.

* * *

Dr. Walter A. Fansler, Minneapolis, took part in a symposium presented at Detroit on February 9 before members of the Michigan Academy of General Practice and the Wayne County Medical Society. Subject of the symposium was problems of the general practitioner.

* * *

Dr. Tauno Ketola, staff member of the Cokato Hospital since September, 1954, was called into service with the Air Force at Montgomery, Alabama, at the end of January.

* * *

Dr. William S. Chalgren, Mankato, spoke at a meeting of the Windom Kiwanis Club on February 8 on the subject, "A Psychiatrist's Approach Towards Juvenile Delinquency."

* * *

Dr. and Mrs. A. B. Rosenfield, Minneapolis, and **Dr. and Mrs. C. L. Sheedy,** Austin, left on February 11 for a six weeks' vacation on various Caribbean Islands. At San Juan, Puerto Rico, both physicians presented papers before medical groups.

* * *

On February 15, **Dr. A. J. Lenarz** left his practice at Browerville for a residency in surgery at St. Joseph's Hospital, St. Paul. He expects to return to Browerville on July 1.

* * *

Dr. Harris P. Hinderaker, Bird Island, was the principal speaker at a meeting of the Bird Island Parent-Teachers Association on February 7. He spoke in connection with the local heart fund drive.

* * *

A radio talk was given by **Dr. F. H. Koenecke,** Lakefield, over station KWOA, Worthington, on February 6. His talk was on "Premature Babies" and was part of the program entitled, "Your Health Hour," sponsored by the Southwestern Minnesota Medical Society and Auxiliary.

* * *

After two years in the Air Force **Dr. R. J. Lindeman** returned to his practice at Paynesville in mid-January. While in service he was stationed at Colorado Springs, Colorado.

* * *

Dr. M. J. Schirber, Grand Rapids, was the principal speaker at a meeting of the Itasca County Historical Society in Grand Rapids on February 7. He discussed medical instruments and methods used by pioneer physicians in Itasca County.

* * *

Dr. L. G. Flanagan, Austin, attended a continuation course in ophthalmology at the University of Minnesota during the first week of February.

Dr. Nicholas H. Zeller, staff member of the Worthington Municipal Hospital since April, 1954, left in mid-January for a two-year tour of duty in the Army.

* * *

Dr. Dean S. Fleming, director of disease prevention and control for the Minnesota Department of Health, has announced that more than 100,000 children in Minnesota may be vaccinated for poliomyelitis this spring. The decision about the vaccination program depends upon the results of a report on the Salk vaccine to be issued at the University of Michigan about April 1. If the report is favorable, Minnesota would accept a supply of the vaccine from the National Foundation for Infantile Paralysis and make it available to physicians throughout the state.

* * *

Dr. Frederic Kottke, head of the department of physical medicine and rehabilitation at the University of Minnesota, was the principal speaker at a meeting of the Minneapolis District Multiple Sclerosis Society on January 18. Dr. Kottke discussed the university's rehabilitation center.

* * *

Dr. C. J. Swendseen, Graceville, arrived in Starbuck in mid-January to take charge of the practice of **Dr. A. F. Giesen**, who was hospitalized at Northwestern Hospital, Minneapolis, due to injuries suffered in a fall.

* * *

The Swedish consul general in Minneapolis announced in mid-January that **Dr. Henry P. Linner** had been decorated by King Gustav of Sweden. Dr. Linner was made a knight of the Order of North Star. He was one of four Twin Cities men honored for achievements in their fields and for their contributions to Swedish-American relations.

* * *

Dr. I. L. Oliver, Graceville, was the guest speaker at a meeting of the Graceville Nurses Association on February 10. He spoke on new methods in heart and lung surgery and new types of anesthesia and sutures.

* * *

The former Mayo Institute of Experimental Medicine, located near Rochester, has been renamed the **Institute Hills Farm.** The change was made because most of the research laboratories of the institute have been moved to the Medical Sciences Building in Rochester. The farm facilities now are used primarily for breeding and holding animals for research.

* * *

The main speaker at a meeting of the Exchange Club in Cloquet on January 24 was **Dr. Kenneth W. Douglas**, superintendent of Sandstone State Hospital. He discussed the problems of alcoholism and narcotic addiction.

* * *

Dr. and Mrs. H. L. Smith left Rochester on January 31 for a trip to Europe. They plan to return in May. Dr. Smith is a retired member of the Mayo Clinic staff.

Dr. Shohei Shirai of the Mesaba Clinic, Coleraine, spoke on the subject of personal health at a meeting of the Women's Club at Bovey late in January.

* * *

Among the speakers at a conference of the Twin City Preschool Education Association at the University of Minnesota on January 22 was **Dr. Edwin Burklund**, St. Paul pediatrician, who spoke on the value of nursery schools.

* * *

Dr. Lewis Hanson, Frost, was elected chairman of the Faribault County Public Health Nursing Advisory Board at the annual meeting of the board in Blue Earth in mid-January.

* * *

Dr. John E. Hildebrand, Bemidji, suffered a severe fracture of one leg when he fell while crossing an icy street in Bemidji in mid-January. His practice was conducted during his convalescence by his associate, **Dr. J. K. Hartjen.**

* * *

Main speaker at the January meeting of the Mankato Association for Retarded Children was **Dr. John Olive**, pediatrician at the Mankato Clinic. His talk was primarily on the Rh factor and kernicterus.

* * *

Dr. Mario Fischer and **Dr. Edward Zupanc**, both of Duluth, were among the new directors appointed to the board of the Duluth Mental Hygiene Clinic at a meeting late in January.

* * *

Common illnesses and practical ways of dealing with them were discussed by **Dr. Viktor O. Wilson**, Rochester-Olmsted County health director, at a public meeting in Rochester late in January. The talk was one of a series on family health being given in the community. Other lecturers in the series included **Dr. R. M. Wilder** on nutrition and **Dr. George Williams** and **Dr. R. L. Faucett** on the development of mental and emotional health.

* * *

Dr. James J. Coll, Duluth, was guest speaker at a meeting of the Arrowhead Society of Medical Technologists at Duluth on January 28.

* * *

Three Twin Cities physicians took part in a discussion of "Surgery of the Heart" on a television program on WCCO-TV on January 30. They were **Dr. Richard Varco, Dr. J. Arthur Myers, Dr. John Briggs** with Mr. Thomas Mulrooney.

* * *

Dr. H. C. Otto, Frazee, who was operated upon at the University of Minnesota Hospitals in November, returned to his home in Frazee late in January. He was not expected to resume his practice for some time.

* * *

"Health and the Child" was the title of an address by **Dr. John K. Butler**, Cloquet, at a meeting of the Parent-Teacher Association in Carlton on January 18.

* * *

The Truman Public School Board has appointed

Dr. M. J. Lester, Truman, to fill the unexpired term of a late member of the board. The term runs until July 1.

* * *

Dr. Russell M. Wilder, emeritus member of the Mayo Clinic staff, Rochester, was honored at a meeting of dietitians and nurses in Rochester late in January. Dr. Wilder recently won the American Medical Association's Goldberger award in clinical nutrition. He is best known for his studies of diabetes mellitus, carbohydrate metabolism and a program for vitamin-enriched bread and flour.

* * *

Dr. S. T. Normann, Waseca, has been named coroner of Waseca County, replacing **Dr. Orvie J. Swenson,** who held the office for twenty-six years.

* * *

Among the speakers at a meeting of the Minnesota Tuberculosis Nursing Council in St. Paul on January 14 was **Dr. F. F. Callahan,** St. Paul, chief of the division of medical services of the Minnesota Department of Public Welfare. He discussed proposed tuberculosis legislation in the state.

* * *

At a meeting of the Dennison village council in January, **Dr. A. M. Nielsen,** Northfield, was named official physician for the village.

* * *

Dr. Ivan D. Baronofsky, associate professor of surgery at the University of Minnesota Hospitals, has joined the Navy for a two-year tour of duty. He reported for service in February with the rank of lieutenant-commander.

* * *

Dr. Royden H. Belcher, Wheaton, was the guest speaker at a meeting of the Graceville Nursing Association at Graceville in January. He spoke on new treatment methods in various types of epilepsy.

* * *

Little-known medical services in the community were described and explained by **Dr. G. M. B. Hawley** at a meeting of the Red Wing Kiwanis Club in January. Among the subjects he discussed were the grievance committee of the Goodhue County Medical Society, surgical conferences, pathology examinations, and hospital services.

* * *

The Duluth Chapter, Minnesota Academy of General Practice, held a special refresher course on "Fluid and Electrolyte Balance" at St. Luke's Hospital, Duluth, on February 18. Four Minneapolis physicians presented talks during the afternoon and evening sessions. **Dr. John LaBree** and **Dr. Richard J. Frey** discussed "Electrolyte Balances in Cardiac and Renal Disease," and **Dr. W. P. Eder** and **Dr. Richard Raile** talked on electrolyte balance in regard to the surgical and pediatric fields.

* * *

Dr. H. F. Helmholz, Rochester, emeritus member of the Mayo Clinic staff and president of the Olmsted County Community Council, was the principal speaker at the annual dinner meeting of the Rochester Community Chest on January 19.

One week after **Dr. John W. Ekblad,** Duluth, retired as St. Louis County coroner on January 1, he fell down an outside stairs while calling on a patient and sustained a hip fracture. During his sixteen years as coroner, which often required strenuous activity, he was never injured. Dr. Ekblad is eighty years of age.

* * *

Dr. Sidney Esensten, Minneapolis, has received a commendation medal for meritorious service while a prisoner of war in Korea from November, 1950, to September, 1953. The commendation praised Dr. Esensten's efforts to render effective aid to sick and wounded comrades in spite of the difficulties imposed by his North Korean captors.

* * *

Dr. George R. Smith has returned to Hutchinson after two years of active duty in the Army. He has resumed his medical practice with **Dr. Elmer W. Lippmann** and **Dr. Dan W. Huebert.**

* * *

Dr. T. S. Eberley, Benson, sustained a severe leg fracture when his car skidded on an icy highway near Benson about the first of the year and overturned, hurling him from the car. He was taken to Miller Hospital in St. Paul for treatment.

* * *

Dr. William B. Halme, who closed his practice in Wadena nearly two years ago to enter the armed forces, has leased a recently vacated building in Wadena. He expects to be discharged from service before June 1 and plans to resume his practice at Wadena immediately.

* * *

Early in January, **Dr. F. W. Calhoun,** Albert Lea, was honored on his seventy-eighth birthday at a surprise party given by friends. Dr. Calhoun is now in his forty-eighth year of practice, all in the Albert Lea area.

* * *

It was announced in January that **Dr. Herman Miller,** Grand Meadow's only physician, had been called into service with the Air Force.

* * *

Dr. John F. Briggs, St. Paul, has been elected to the Horseshoe Club of London, England, an organization whose object is to foster friendship between American, Canadian and English men and women interested in the cure and prevention of disease.

Dr. Briggs has also been asked to act as a collaborator for *Medico-Surgical Annals,* a new magazine which will stress diseases of the chest and thoracic surgery. The magazine will be published in Spain.

* * *

Dr. Gordon R. Kamman, St. Paul, spoke on "Psychological Evaluations in Medical Practice" at a meeting of the Sixth District Medical Society at Bismarck, North Dakota, on February 22.

NEW LOCATIONS

Dr. Carl Anderson, formerly of Miles City, Montana, has been appointed resident physician at the Minnesota State Penitentiary at Stillwater.

* * *

Dr. Carl Heinzerling, formerly of Watertown, has opened offices for the practice of medicine in Chaska.

* * *

Dr. A. L. Ourada, Ceylon, has opened an office at Fairmont. He now maintains office hours in Fairmont in the morning and in Ceylon in the afternoon. He expects to move to Fairmont in June.

* * *

Dr. Edward Menefee, who recently completed a residency in pathology at Rochester, is now associated with the Naeve Hospital, Albert Lea, as a pathologist.

* * *

Dr. John Meyers, formerly of Chicago, has become associated in practice with **Dr. L. J. Monson** in Canby.

MINNESOTA BLUE SHIELD-BLUE CROSS

Blue Cross News

During the month of December, 1954, 18,870 participant subscribers were enrolled in Blue Cross bringing the net enrollment as of December 31, 1954 to 1,000,051 participant subscribers.

The amount of hospital care benefits received by Minnesota Blue Cross subscribers during 1954 amounted to $18,272,129.50, an increase of $2,822,556.55 over the amount provided in 1953.

During the past year, 165,989 Blue Cross subscribers were hospitalized for a total of 1,003,552.3 days of care. Average length of stay in the hospital for a Blue Cross patient was six days.

The four major causes for hospitalization of Minnesota Blue Cross subscribers during 1954 were: pregnancies, injuries and accidental poisonings, respiratory ills and digestive illness. There were 28,579 pregnancy cases of which 5,612 were for pyelitis of pregnancy, toxemias, ectopic, et cetera, and 22,967 were deliveries amounting to over 2½ million dolllars in benefits. There were 25,306 injuries and accidental poisonings amounting to over one million dollars in savings to subscribers. Over 1½ million dollars in benefits was provided for 22,703 subscribers who had respiratory illnesses. 21,996 subscribers had digestive ailments of which 11,600 were surgical cases. A total of approximately $3,200,000 was paid in benefits for digestive diseases alone.

Since 1933 when Blue Cross was first started here in Minnesota, 1,729,994 subscribers have spent 10,479,006.6 days in hospitals and have received benefits amounting to $110,949,752.

Blue Shield News

In the year 1954, payments to doctors for services rendered to Blue Shield subscribers totaled $4,970,000. This amount marks a new high in the annual amount of money paid to doctors. For the year 1954, payments have been over $700,000 more than was paid in 1953. Further analysis shows that the payments made in 1954 are 16 per cent greater than the amounts paid in the preceding year, 1953. The dollar increase in 1954 was due principally to the increased benefits which became effective on January 1, 1954, but also to the increase in the number of services rendered by doctors of medicine.

Another interesting factor in the growth of Blue Shield is revealed in the compilation of data which discloses that during 1954, 169,445 services were rendered by doctors for which Blue Shield provided allowances. This can be compared with a total 148,561 compensable services rendered during the year 1953.

Internal changes have also been made in the Blue Shield organization in order to provide more time to disseminate information to members of the medical profession regarding the Blue Shield contract and procedures. These changes have been of some help in the doctors' offices and have led to greater efficiency in Blue Shield. In this particular field, many of the problems which have formerly existed were eliminated through professional relations activities in 1954. This program is continuing and is being expanded as rapidly as possible.

Blue Shield enrollment as of December 31, 1954, totaled 670,757 participant subscribers. Enrollment as of December 31, 1953, was 609,474 participant subscribers. This represents slightly more than an 11 per cent increase in enrollment throughout the year 1954.

ATHLETIC ACCIDENT BENEFIT PLAN

(Continued from Page 183)

Control approved an increase to $3 per year for the boy who participates in football alone or football and other sports, and $1.50 per year for the athlete not playing football. It is hoped and intended that this will take care of the increased payments.

Your medical service committee and H. R. Peterson realize that there are a number of problems still to be solved and that there always will be administrative and public relations items to be considered. I assure you that utmost co-operation can be expected from the league and its medical advisor, and improvements will continue to be made. Comments and discussions from the physicians of Minnesota are more than welcome at any time and at all times.

Appreciation is expressed at this time to Dr. J. A. Bargen, chairman of the Medical Service Committee of the Minnesota State Medical Association, and his committee for their energetic help and advice in the 1954-1955 revision of this program.

Original Contributions

Polypoid Rhabdomyosarcoma of the Bladder: Sarcoma Botryoides

BAXTER A. SMITH, JR., M.D.
Minneapolis, Minnesota

AT the risk of seeming heretical, I would suggest that the clinical term "sarcoma botryoides" replace the more scientific pathologic term "rhabdomyosarcoma." If the latter designation is employed, the adjective "polypoid" should precede it, since sarcoma botryoides of the bladder appears to be a clinical entity. This stand is taken in the expectation that the clinical appearance is typical enough to promote early diagnosis and proper treatment. However, I am in complete accord with McFarland,[9] who showed it to be one of the manifestations of dysontogenetic tumors of the urogenital region; he found 119 different names used for this tumor in 516 references. Rhabdomyosarcoma of the prostate is no doubt the same lesion with a different appearance because inadequate room for expansion prevents the pronounced edema and the polypoid appearance.

Botryoid sarcoma is a polypoid, usually diffuse, edematous-appearing, grapelike tumor, involving the vesical submucosa. It arises in the region of the trigone or internal meatus and tends to produce obstruction early. It spreads through the submucosa to the adjacent bladder, posterior urethra and ureters. It is not feasible grossly to determine the margin of the tumor involvement. Infiltration in depth occurs considerably later. Local extension occurs and distant metastasis (regional lymph nodes, liver and lungs) is fundamentally a late manifestation. Once the lesion escapes the confining viscus, because of surgery or infiltration, rapid, and massive extension or local recurrence is the rule. Its "seeding" tendency seems pronounced.

Based on the behavior just described, the potential prognosis is good. In rhabdomyosarcoma of the adult bladder, the lesions seem to be single and pedunculated and may arise at a distance from the trigone; by description, they are not botryoid but no doubt have the same origin. Sarcoma botryoides occurs in the vaginas of little girls, resulting quickly in protruding polypoid masses. It occurs in the cervix in the middle years and the uterus in later years. The lesion may involve the soft palate also.

The microscopic picture shows edematous loose myxomatous stroma, in some areas fairly dense. The typical cell is spindle-shaped with acidophilic cytoplasm showing longitudinal fibrillae and cross striations. These latter may require phosphotungstic acid or iron-hematoxylin stain for identification; if searched for they usually are present and diagnostic. Mostofi and Morse[10] describe large spherical cells with a small amount of acidophilic cytoplasm and multinucleated giant cells as noted by several pathologists. As McFarland pointed out, the cells may be of mixed types and in varying stages of differentiation.

The bladder tumor is presumed to be of Wolffian-duct origin in the region of the ureteral orifices and trigone and is dysotogenetic, though the fibers of the external urethral sphincter or the prostatic capsule are postulated as the origin by some. Swinney[12] described a small pedunculated narrow growth protruding from the posterior urethra into the bladder at cystotomy. The recurrence was typical, diffuse botryoid sarcoma, and the initial description is likely that of a very early lesion. Cervical and vaginal origin could be from the duct of Gartner, a Wolffian-duct structure, or it may be from the Müllerian duct; most tumors in this location originate in the proximal vagina or the anterior wall.

The incidence of this tumor is much greater than reported cases would indicate, although the

---

Presented before the Minnesota Academy of Medicine, February 10, 1954.

lesion is uncommon. In addition to the two cases here reported, I have knowledge of another seen in Minneapolis. Grier and Phillips,[4] in 1953, stated that twenty-two cases had been reported but did not include at least twenty-eight reported since their article was submitted for publication. Many tumors have been reported as myxosarcoma or myxoma,[2,5,9,11] but the clinical findings fit sarcoma botryoides and the striated muscle cells have not been sought or seen. McFarland collected seventy-seven cases of dysontogenetic bladder tumors; in sixty-one the patients were less than twenty-two years of age and almost all of the lesions were very soft. Higgins[6] reported a series of four cases.

Though Youngblood and associates[13] stated that the sex incidence is even, it would seem that males are afflicted in a frequency of 3:1. The age varies from that of the newborn, as in Hunt's[8] case, in which complete retention occurred at the age of five days, to twelve years, but most patients are less than four years of age. Adults have had rhabdomyosarcoma of the bladder, but apparently these were not sarcoma botryoides.

The prognosis has been given as uniformly bad. Only two children with such tumors have been reported as well two years after diagnosis. One of these, a boy, was well seven years after cystectomy, according to Flocks[3]; the other, described by Higgins, was a girl who was well two years and nine months after cystectomy. Higgins and associates[7] describe a "myxoma" which prolapsed through the urethra of a girl at birth; a ligature was applied. Cystoscopy at four weeks showed a scar at the region of the left ureteral orifice. Some "vesicles and thickening" were fulgurated upon two occasions. Four years later, the patient was well, and cystoscopy gave negative findings. Subsequently, the tissue was re-examined and found to be typical of rhabdomyosarcoma. Most patients are dead or dying of recurrence within a year, though Swinney's patient did not have recurrence until twenty-five months after definitive surgery. However, many authors have pointed out that the potential cure should be great, and it is probable that if the disease is understood, successful therapy will not be such an exception. It is imperative that those seeing the relatively few cases be familiar with the disease.

Symptoms are those of urinary obstruction, infection and hematuria. Obstruction occurs early. As one of the "grapes" tends to prolapse, giving obstruction, hematuria usually occurs at some time in the disease. In female patients, the masses may prolapse, and occasionally some "grapes" may be passed. Spasmodic pain from the obstruction to urination and prolapse of an edematous mass may be intense; pain may be due to secondary infection. The patient may have intermittent or continuous evacuation of urine or may have complete retention.

A mass is almost always present and is usually the distended bladder. After catheterization, the mass usually persists on bimanual palpation. It is moderately soft and somewhat movable, depending upon the state of the disease. The kidneys may be palpable due to ureteral obstruction. As already mentioned, there may be prolapse of a "polyp" through the urethra in the female patient, and, if the disease is extravesical, rapidly enlarging, edematous masses may protrude from the vulva or vagina. In a case described by Canard and Rivarola,[1] the urethra in a two-year-old girl had been so dilated by a prolapsing "polyp" that digital examination and biopsy of the bladder were feasible. The urine may be normal but usually shows red blood cells and pus. Fever may be present, and renal function is likely to be impaired in variable degree. The patient may be cachectic and show evidence of obstruction to venous and lymphatic return from the lower extremities.

X-ray examination should be performed by excretory urography, if the renal function allows. This will show the status of the upper urinary tract and, if function is adequate, give a satisfactory cystogram. If not, retrograde cystography will show a picture typical, but not well-known, in the roentgenologic or pediatric literature, as determined by my scanty perusal thereof. This appearance is of multiple filling defects, usually smooth and involving the base particularly and the prostatic urethra frequently. The lesions are sometimes described as "lacunar." As in Case 1, others have confused the filling defect picture with "rectal gas."

Cystoscopy is usually feasible in contrast to sarcoma of the prostate. Interpretation may be difficult because of the presence of bleeding and infection and the use of small instruments, but the picture should be diagnostic. Multiple, pearly white, semitranslucent polypoid structures are seen. The region of the trigone and internal meatus almost always is involved. The appearance has been likened to hydatidiform mole, and Canard and Rivarola compared the bladder to the inside of a hydatid (echinococcus) cyst filled with daughter cysts. Transurethral biopsy should be done to verify the clinical diagnosis so that one will have pathologic backing to bolster one's courage for the necessary undertaking in a young child. The bladder should not be opened. The grapelike masses may be cut or broken off without fear of untoward bleeding and are diagnostic pathologically.

The differential diagnosis should include polyps of the verumontanum. If there is a question of the lesion's nature, resection rather than fulguration only should be done so that material for biopsy may be obtained and an early lesion discovered. Edema from adjacent processes such as an appendiceal abscess may be confusing. An ureterocele, which may prolapse through the female urethral meatus, or which may be inflamed, edematous and located intravesically, must not be mistaken for botryoid sarcoma.

Report of Cases

Case 1.—A fifteen-month-old white girl was hospitalized March 12, 1948. "Vaginal prolapse" was first noted in December, 1947; in January, 1948, "prolapsing bladder mucous membrane" was partially excised and the remaining portion reduced. Two days prior to admission, there was prolapse of the rectum and what was believed to be uterus; again "bladder mucosa" protruded. No complaints referable to voiding were noted, but the rectal prolapse was probably due to straining to urinate.

Examination revealed a large firm purplish mass protruding from the vulva. The next day an observer stated the mass had increased no less than four times in size. Blood urea nitrogen was 24 mg. per 100 cc. Catheterized urine was normal except for 1+ pus cells. Excretory urography showed bilateral hydronephrosis and hydroureter and deformity of the bladder base believed due to rectal gas.

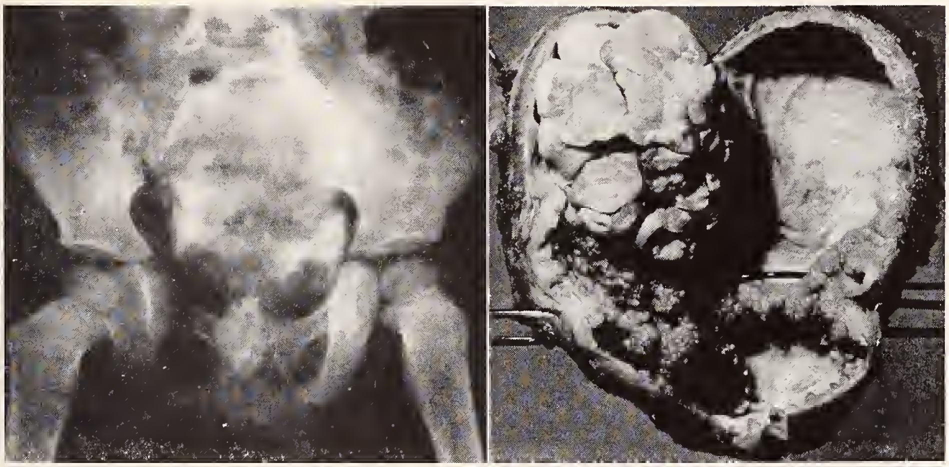

Fig. 1. *(left)* Case 2. Excretory cystogram. Note smooth filling defects in the bladder, particularly at the region of the internal meatus, and the dilated posterior urethra with filling defects.

Fig. 2. *(right)* Case 2. Frontal section of the bladder, fixed in distention. The ureteral catheter identifies the position of the ureteral orifices. Note tumor nodules in the prostatic urethra.

At cystoscopy, the urethra was found posterior to the vulval mass; the meatus was not dilated and no mass protruded from it. There was marked edema of the anterior bladder wall at the internal meatus. Trabeculation was present in the fundus. The right ureteral orifice was identified, but not the left. The vulval mass seemed attached by a broad stalk of tissue going anterior to the urethra. There was thickening noted on rectal examination. The vesical changes were interpreted as secondary to extravesical tumor, and biopsy of the mass showed malignant mixed tumor, predominantly myxoma. The retrograde cystogram, in retrospect, was quite typical of botryoid involvement near the internal meatus.

On March 19, the large lesion anterior to the urethra was dissected upward, displacing the bladder posteriorly. The tumor fanned out in a sheet across the anterior bladder wall; biopsy at the line of excision resulted in a diagnosis of myxosarcoma. The excised mass measured 3.5 x 3 x 2 cm. and the bladder was then felt to be 4 x 3 x 2 cm. with thickening out of proportion to hypertrophy. Botryoid sarcoma was then believed to be the diagnosis; since involvement extended beyond the bladder, total excision was not deemed feasible. It is probable that the lesion spread to the retropubic area from the vulva rather than by penetration of the urinary tract.

On April 6, 1948, transverse colostomy was done by Dr. David State, and the bladder was estimated at 5 x 3 x 2 cm. One month later, he removed the bladder, uterus, vagina and vulva transplanting the ureters to the sigmoid. Two peritoneal nodules were present over the bladder, and several nodes were involved with tumor.

The specimen showed a large fungating tumor composed of grayish-yellow, somewhat rubbery tissue. Penetration occurred through half of the bladder wall. There was a tumor nodule measuring 2x1x1 cm. in the vagina. Microscopic examination showed spindle cells of fairly uniform size in a stroma that in some areas was fibrous and in some areas myxomatous.

The girl was discharged on May 18, 1948, and was readmitted in August, 1948, because of prolapse of the colonic stoma. Recurrence was noted on rectal palpation; the child died in February, 1949.

Case 2.—A two-year-old white boy was first seen on January 16, 1953. Two months previously, he had mild hematuria, and an excretory urogram was presumably negative. From that time on, he had variable but progressive difficulty in voiding, and at the time seen he was dribbling almost continually. At times, pain seemed rather intense and he awakened from sleep in pain. He would rub his penis and cry. Fecal incontinence occurred with straining to void.

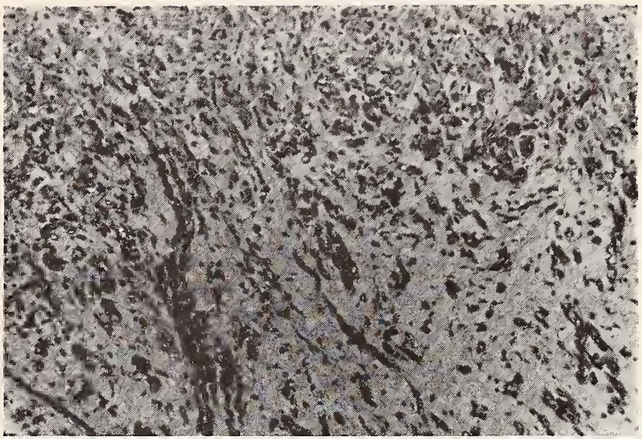

Fig. 3. *(above)* Case 2. Low-power view of the tissue, myxomatous below and more cellular above; acidophilic bands are prominent.

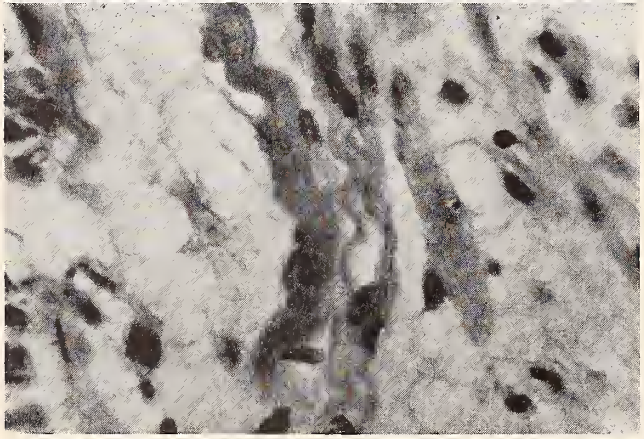

Fig. 4. *(below)* Case 2. High-power view showing myofibrillae and cross striations.

Examination revealed a palpable tender bladder. The urine contained 2+ albumin, a few red blood cells and packed fields of leukocytes. Excretory urography demonstrated slight dilatation of the lower ureters and a typical cystogram (Fig. 1).

At cystoscopy, landmarks were difficult to recognize. The typical white grape-like masses were present, mainly in the anterior wall and surrounding the internal meatus. There was trabeculation and cellule formation in the fundus and base. Several small masses were excised for biopsy. A moderately soft mass extending well toward the umbilicus was present on bimanual palpation.

Microscopic examination showed a markedly edematous stroma and chronic inflammatory exudate in the submucosa. In this stroma were thick pink-staining bands with cross striations in some.

On January 23, 1953, prostatovesiculocystectomy and regional lymphadenectomy were performed. The urachus was severed at the umbilicus; the urethra was divided 2 cm. below the prostatic apex. The ureters were transplanted to the rectosigmoid in a modified Leadbetter manner, leaving a rather long loop of sigmoid proximal to the anastomosis so that terminal colostomy might be performed later. The child's bladder is more intraperitoneal than the adult's, facilitating cystectomy somewhat

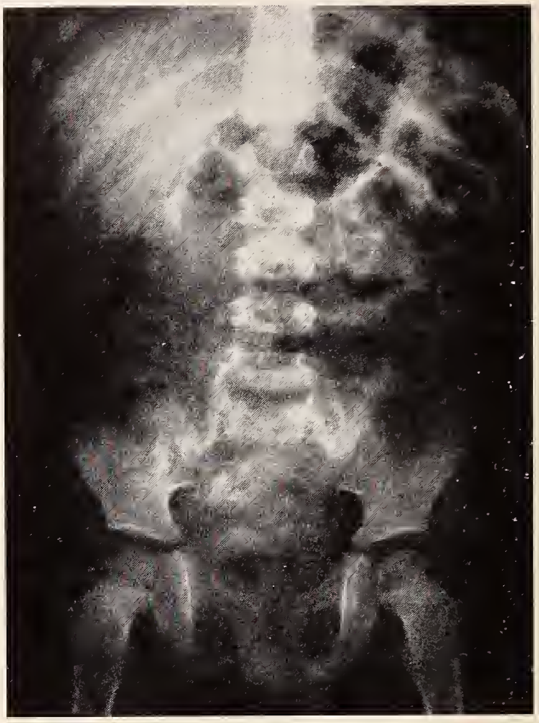

Fig. 5. Case 2. Excretory urogram 6 months after operation.

Pathologic examination showed diffuse involvement of the bladder and posterior urethra (Fig. 2) and one nodule in an intramural ureter. Sixteen identified nodes showed no evidence of malignancy. The microscopic picture was similar to that of the material removed for biopsy (Figs. 3 and 4). Invasion of muscle was not seen.

Convalescence was uneventful. An excretory urogram on the fourteenth postoperative day was normal, and the patient was dismissed the next day.

The boy was seen June 17, 1953. Blood chemical values and the urogram were excellent (Fig. 5), and the only suspicious finding was a small nodule at the site of one of the stay sutures. This was excised and a stitch abscess with a bit of silk was found. Bimanual examination and palpation of the urethral bulb gave negative findings. The grandparents reported that in January, 1954, the boy was well and prospering. Terminal colostomy is planned later.

Comment

In almost all instances of this disease, the urinary tract has been opened prior to definitive surgery, and the speed and magnitude of local recurrence are impressive. Renal function was destroyed or the disease had extended prior to seeking medical care at times. A high index of suspicion is essential to early diagnosis. This disease seems to be a clinical entity, and from the cystogram, cystoscopy and palpation under anesthesia, diagnosis should be accurate. Cystoscopic biopsy is feasible, but suprapublic biopsy is contraindicated.

Prompt cystectomy, including the urethra in female patients, the prostate, seminal vesicles and a liberal portion of adjacent urethra in male patients and a segment of adjacent ureter in both, should be performed. In female patients, the uterus and at least the upper half of the anterior vaginal wall probably should be excised. The method of urinary diversion is another subject. Irradiation is ineffectual and is thought by some to stimulate the tumor to more rapid growth; fulguration has the same reputation.

Summary and Conclusions

1. Two cases of sarcoma botryoides have been reported: One patient died, whereas the second patient was well eleven months following radical cystectomy.
2. Sarcoma botryoides or polypoid rhabdomyosarcoma of the bladder in children seems to be a clinical entity and the descriptive former term is suggested as perhaps more appropriate in stimulating earlier recognition of the disease.
3. Familiarity with the nature of the lesion should lead to early diagnosis.
4. Opening the bladder or cutting into the tumor usually is followed quickly by massive local recurrence.
5. Radical cystectomy should be undertaken forthwith, including a liberal proportion of the adjacent urethra and ureters.
6. The prognosis of the tumor should not be as bad as the statistics to date would indicate.
7. It is believed that sarcoma of the prostate is the same lesion with a different gross appearance.

Addendum

The second patient (Case 2) was well when last seen, June 30, 1954.

RETREATMENT OF CERVICAL CANCER

Two Mayo Clinic radiologists have published a review of results in *retreatment* of cervical carcinoma.

Their conclusion: "The impression that prognosis is largely determined at the time of primary diagnosis and treatment is partially refuted."

The two doctors are Martin Van Herik and Robert E. Fricke, from the section of therapeutic radiology at the Mayo Clinic. Their review and report appears in the March issue of the *American Journal of Roentgenology, Radium Therapy and Nuclear Medicine.*

One hundred and ten patients with recurrent cancer of the cervix, treated by irradiation, during 1940 to 1947 were studied. Of the entire group: twenty-five patients (22.7 per cent) lived more than three years following treatment for the recurrence; eighteen patients (16.4 per cent) lived more than five years.

"This result is far from excellent, but it is sufficient to refute partially the impression that the prognosis is largely determined at the time of primary diagnosis and treatment," report Drs. Van Herik and Fricke.

"Furthermore, detailed study of the records of our patients who did not survive at least three years following treatment for recurrence reveals that in a great many cases a worthwhile palliation was achieved," they add.

The Southern Minnesota Medical Association

WILLIAM C. BERNSTEIN, M.D.
Saint Paul, Minnesota

A PRESIDENTIAL address which is to be delivered as an after-dinner speech must of necessity be conceived and written with the proverbial two strikes against it. I have listened to many presidential addresses at this and at other meetings, and I am well aware of the necessity for brevity and alacrity in order that the speaker remain in the good graces of his audience. I shall try to remain in your good graces.

This has been a most pleasant year for me. To have served as your president and to have had the privilege of working closely with the other officers and committee members has been an honor and a pleasure which I shall long cherish. I completed my internship at the Ancker Hospital in Saint Paul and then began the practice of medicine at New Richland in Waseca County in 1928. In 1929, I became a member of the Southern Minnesota Medical Association and read my first paper at the annual meeting which was held in Mankato. I am therefore, in 1954, celebrating my silver anniversary as a member of this organization by speaking to you as your president.

The Southern Minnesota Medical Association has played a most significant role in my professional career. It provided me with the opportunity through the years not only to listen to many outstanding medical speakers, but to read papers, report cases and participate actively in the affairs of this dynamic medical society. It has given me the inspiration, which is so vital in a young medic's life, to work towards higher goals. What membership in this organization has done for me, it can do for every young physician who practices in southern Minnesota. This society actively solicits the interest and participation of its younger members. The officers of this society are most happy to have papers submitted by all of its members. The program committee works zealously to build a program that will interest everyone and which will stimulate others to submit papers for future meetings. I urge our membership to be active members in the society. Our organization, since its inception, has been a vital force in Minnesota medicine, and from the quality of the program which was presented here today, there can be no doubt as to the future status of this organization.

It may be of interest to point out a few important historical facts concerning the Southern Minnesota Medical Association. Dr. Monte C. Piper of Rochester delivered an address on this subject at the meeting in 1935, and I have selected a few interesting details from his paper. We are meeting today in the city which witnessed the birth of this society on July 28, 1892. The letters inviting the doctors in this area to an organization meeting were sent out by a group of Rochester physicians. Thirty-five physicians attended, and the association was founded on that day. The committee on permanent organization consisted of Drs. W. T. Adams of Elgin, W. J. Mayo of Rochester and J. B. McGaughey of Winona. The dues were fifty cents a year. The first paper was presented by Dr. McGaughey on "Cerebrospinal Meningitis"; the second paper was by Dr. W. J. Mayo on "Less Common Forms of Surgical Tuberculosis."

Twelve years before the organization of the Southern Minnesota Medical Association, the Minnesota Valley Medical Association was organized at Le Sueur on December 1, 1880. This society adopted the by-laws of the Ramsey County Medical Society as a foundation for its government. Dr. Otis Ayer of Le Sueur was honored by being chosen the first president.

At a joint meeting of the Minnesota Valley Medical Association and the Southern Minnesota Medical Association held in Rochester in 1911 the two societies amalgamated, and the Southern

---

Presidential address presented at the annual meeting of the Southern Minnesota Medical Association, Winona, Minnesota, September 13, 1954.

Minnesota Medical Association as its exists today came into being. The Minnesota Valley Medical Association which had existed for thirty-one years contributed 105 members, while the Southern Minnesota Medical Association which was nineteen years old contributed 115 members. Dr. L. A. Fritsche of New Ulm was elected president of the amalgamated societies.

As the Southern Minnesota Medical Association grew in scope and influence, rumors arose that this society was a threatening rival to some of the larger medical organizations. Talk of further expansion and competition with the Minnesota State Medical Association and the Tri-State Medical Association was put to an end by Dr. W. J. Mayo in 1919 when he stated, "Dr. Andrews has said that the association is equal to, if not greater than, the state association. I want to say to you, members of the Southern Minnesota Medical Association, that this should not be true, that every man who is here is potentially a member of the state medical association, and he should attend the meetings of the state medical association as the representative body of the state. After all, we are a local society, but we have great traditions."

I believe that time has proved the wisdom of Dr. Mayo's admonitions. This society is a local, nonpolitical organization which fills a definite need in the professional life of the physicians in southern Minnesota. We encourage the preparation and presentation of scientific papers; we encourage higher scholastic attainments in medical school by our annual awards to the most outstanding senior. We encourage scientific exhibits at the annual meeting of the Minnesota State Medical Association by awarding a medal for the best scientific exhibit, and we are an organized unit to enhance the quality of medical and nursing care in Minnesota.

Anyone who has listened to the wide variety of excellent papers presented at our meeting today must be impressed with the facts that we are now discussing many subjects almost undreamed of twenty years ago, such as, "Radio-isotopes in Diagnosis," "Cortisone Therapy," "Pulmonary Hypertension" and others. Also, of course, it is no longer possible for one person to be well informed on all phases of medicine. Dr. Aura E. Severinghaus, writing in a recent issue of *The Journal of the American Medical Association*, said, "The first half of this century will always be known as 'a scientific age.' Among the major accomplishments of science, history will record the conquest of disease. Progress in this area has been spectacular beyond all expectation. With it has come, however, an almost staggering expansion of our scientific knowledge. More than ever before it has become necessary for those who wish to keep professionally informed to increase their scientific information. More than ever before it has become obvious that no person should even attempt to encompass the entire body of facts. This has naturally increased the emphasis on science in the future physician's education and resulted as well in a high degree of specialization in today's medical practice. The end is not yet in sight. I am reminded of a friend who recently hailed a taxicab in front of the Bureau of Archives in Washington. As the cab drew up he was still repeating audibly the inscription over the front entrance, 'The Past is but a Prologue.' 'Do you know what that means?' he said to the driver, and, as is characteristic of Washington cab drivers, the driver quickly replied, 'Yes sir, that means you ain't seen nothin' yet.' "

I would like now to make some comments relative to the practice of medicine in Minnesota in general and in southern Minnesota in particular. It is well to take inventory once in a while to evaluate our own assets and our own liabilities or shortcomings. I am certain that no one would contradict me when I state that the standards of medical practice in this section of our country are of the very highest. I know of no area where medical practice, be it of the general practitioner in the small community or of the specialist in the larger city, is on a higher plane. I know of no place in this entire country where postgraduate courses, tailored to fit the needs of the physicians practicing in the state, are made so readily available. Is there a reasonable explanation for this situation? The answer, I am sure, lies in the presence in our midst of two of the world's greatest institutions of medical teaching and research, namely, the University of Minnesota Medical School and the Mayo Clinic with its associated Mayo Foundation. Those of us who practice so close to these institutions of world renown begin, after a while, to take them for granted and to disregard the enormity of the roles played by them in medical progress. Need I mention more to you than the contributions of Hensch and his co-workers at the Mayo Clinic in the development of cortisone, and the epoch-making advances in cardiac surgery recently announced at the University of Minnesota Hospitals, to remind you of the atmosphere in which all of us live and practice? We are sometimes blinded by our proximity and, to use a trite expression, we fail to see the forest for the trees. We need but to travel to other states or other countries to be impressed with the overwhelming stature of these two institutions. How often do we hear or participate in derogatory discussions concerning these institutions? Would anyone have to stretch his imagination to believe or to admit that medical practice has attained its high level here because of the influence of our great medical centers? Could one dare to imagine what would happen to the standards of medical practice in this area were we to lose one or the other —or both—of these institutions? We who practice here are the beneficiaries of one of the richest medical legacies in history. Let us not treat our legacy too lightly.

The practice of medicine in Minnesota is different in other ways, too, from the practice of medicine in some other locales. We hear too often of contending factionalism and of bedeviling provincialism in medical practice. Fortunately for us, we experience few of these evils in Minnesota. The spirit of co-operation at hospital staff and county society levels is everywhere apparent. I believe that few states can boast of better records in this regard.

I would be amiss in my responsibilities, however, if I did not point out one of our most flagrant shortcomings. It is a well-known fact that Minnesota ranks high in the incidence of malpractice suits. It is paradoxical that this should be true. Our state society has had a hardworking committee assigned to this problem for many years. The situation has shown little improvement thus far, and our medical malpractice insurance rates continue to rise. Everyone seems to be agreed that most suits are initiated or encouraged by misdirected remarks on the part of other physicians. This problem can and must be corrected if we are to maintain a position where we can use our initiative in treating patients without having the threat of malpractice forever dangling over us.

One of the great problems facing the medical profession here and elsewhere is the shortage of nurses. It is interesting and gratifying to learn that the situation in Minnesota is not as bad as it is in many other states and that our schools of nursing are turning out more nurses in all categories than in previous years. Although Minnesota ranks eighteenth among the other states population-wise, it ranks fifth in the number of nurses it turns out. Hospitals are learning that many duties can be delegated to nonprofessional personnel and that the nursing team consisting of a registered nurse, a practical nurse and several nursing aides can function well as a unit in caring for large numbers of patients. We are fortunate in having progressive and mature leaders to encourage and educate large numbers of young women for nursing careers. The outlook for the future is brighter than it has been for many years. This society has a very active committee on nursing which has made some valuable contributions to the nursing program.

In conclusion, may I once again urge the younger men to participate actively in the affairs of this society and may I impress upon you the privilege which is yours of practicing medicine in an area where the light of medical learning and of high standards of practice and ethics shines so brightly upon all the members of our profession.

Puerperal Psychoses

E. M. HAMMES, JR., M.D.
Saint Paul, Minnesota

ACUTE psychotic symptoms develop as a complication after pregnancy about once in every 600 deliveries. The frequency varies slightly with different authors, due to different criteria for diagnosis. Prior to the advent of obstetrical asepsis and antisepsis and the development of antibiotics, mental illness occurred much more frequently, due to the high incidence of toxic delirium associated with puerperal sepsis. In the present era toxic reactions are rare, and the clinical picture in the psychoses after childbirth is that of a depression, schizophrenia or occasionally a manic reaction. As a result, the clinical course of these illnesses in modern times is prolonged but the mortality is low. In the puerperal toxic psychoses of an earlier day the patient recovered or died very promptly. Today the mortality results from an occasional suicide, or more rarely from catatonic or manic exhaustion.

There is a tendency to drop the term "postpartum psychosis" from current literature. Modern psychiatric textbooks devote little or no space to it, apparently preferring to classify these illnesses with the usual functional psychoses. This we feel is a mistake. The terms postoperative and involutional psychosis are commonly and properly used, and the diagnosis postpartum psychosis should be likewise preserved. We feel that there are differences between the postpartum and other psychoses which warrant their being classified as an entity. The illness carries a distinct threat to the newborn infant and, in addition, differs in its course, prognosis and frequency of recurrences, in comparison with other "functional" psychoses. These differences should be emphasized, and can be done so only if the postpartum psychoses are classified in a separate category.

The term postpartum psychosis should be reserved for those cases which meet all the following three criteria: (1) The onset of symptoms is during the first six weeks after the termination of a known pregnancy—the common obstetrical definition of the puerperium. (2) The patient has no past history of other psychotic reactions. A previously schizophrenic or manic-depressive patient who has a relapse after delivery cannot properly be classified in this group; however, recurrences of the disease after succeeding pregnancies can occur and are consistent with the diagnosis. (3) The patient must have an actual psychosis. This eliminates the more common, often transient, exhaustion syndromes and neurotic reactions which occur at this period.

We have reviewed our experience over the last several years with forty-three cases of this condition, in an attempt to find some indication which would make possible the detection during pregnancy of the woman who will develop a postpartum psychosis, as a step toward prevention of this complication. Our patients were compared with two groups of controls. The first consisted of psychotic married women of the same age distribution, whose mental illnesses developed unrelated to pregnancy and delivery. In comparing our patients with this group, no differences could be found in the age of marriage, age of childbirth, family history of psychoses, position of the patient in her sibling pattern, prepsychotic personality traits, educational background or frequency of environmental stresses. In each group there was a family history of mental illness in about 30 per cent of the patients. In both the postpartum group and this control group, about one-half of the patients had a prepsychotic personality considered to be normal and well adjusted by their families; the balance were described variously as "excessively nervous," withdrawn or overly meticulous and perfectionistic.

The second control group consisted of a series of married women in the same age range, who had no psychotic symptoms. These were for the most part patients with organic neurologic disease.

Presented at the annual meeting of the Southern Minnesota Medical Association, Winona, Minnesota, September 13, 1954.

In comparison with this group appreciable differences were seen in the family history of psychoses and in the personalities of the patients. Only four of these forty-three control patients had a positive family history of mental illness, and twenty-nine were considered to have stable and well-adjusted personalities.

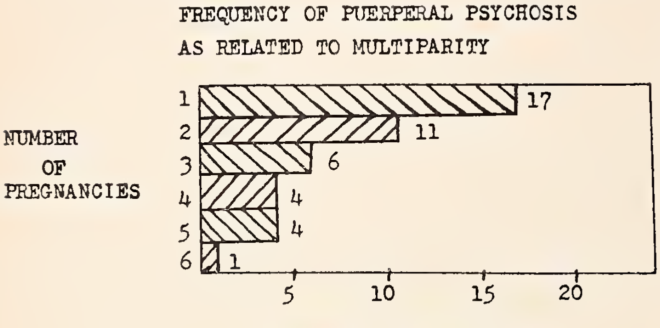

Fig. 1.

The patient who is destined to have a postpartum psychosis is more likely to have a history of mental illness in her family and a past history of an unstable personality than is a non-psychotic woman. But these factors occur with about equal frequency in women who develop psychoses not related to parturition. Thus one can predict a postpartum psychosis in a pregnant woman with about the same degree of accuracy as one can predict a functional psychosis before it occurs. This agrees with the statement of Strecker et al[1] that the puerperal period may precipitate a psychosis, especially if there is evidence in the patient's personality makeup of either manic-depressive or schizoid tendencies.

Puerperal psychoses occur rarely following abnormal pregnancies or premature deliveries. In thirty-nine cases the pregnancy and labor were entirely normal. One patient had a cesarean section and one a postpartum hemorrhage following which the patient's hemoglobin dropped to 40 per cent. Toxemia of pregnancy occurred in the two other complicated cases. Of these one occurred antepartum and was mild. The other patient had severe eclampsia with convulsions immediately postpartum, and the associated psychosis was toxic in type. In each of the 49 psychotic episodes which occurred in these 43 patients the pregnancy resulted in a living, healthy child born at full term. There was no instance in this group of a postpartum psychosis developing after an abortion, miscarriage, premature labor, stillbirth, or after the delivery of a deformed or abnormal baby. These forty-three women have had a total of 126 pregnancies. Of these, twelve have ended tragically with a dead or deformed infant without a single instance of puerperal psychosis. The remaining 114 pregnancies, which all resulted in apparently normal children, were followed in forty-nine instances by mental illness. While the series is too small to permit definite conclusions statistically, it does suggest that death or deformity of the child does not predispose to the development of a puerperal psychosis and may actually decrease the possibility of a mental illness after delivery.

The likelihood of a puerperal psychosis is greater in primiparas and early multiparas than it is in women who have had several pregnancies. Of the forty-three women, seventeen were primiparas, and thirty-four developed their first psychosis after one of the first three pregnancies. There was one patient whose mental illness did not develop until after the sixth pregnancy (Fig. 1). The various types of psychoses occur in about the same ratio as do the usual functional psychoses in this age group. The implication is that whatever role the pregnancy and delivery may play in precipitating the illness, the type of mental reaction which results is determined by the patient's own personality makeup and by other factors unrelated to the pregnancy. Our patients included eighteen with depression, one with a manic psychosis, fifteen with schizophrenic reactions, eight with disorders which were classified as schizo-affective, and one with toxic delirium. As a group they showed a pronounced tendency toward suicidal impulses and toward homicidal threats against the newborn infant. Eight of the patients were considered suicidal risks, and six expressed definite desires to harm their babies. These two factors place a great responsibility on the obstetrician in the early recognition of psychotic symptoms and the prompt protection of the mother from harming herself or her child.

Results of Treatment and Follow-up

On the whole the prognosis for recovery from puerperal psychoses is gratifying and better than the average for the usual functional psychoses in this age group. Five of the patients were not hospitalized, either because the family refused it or because the illness was mild enough to permit out-patient treatment. Of these five, four made steady improvement to recovery and one a social remission. A two- to five-year follow-up of four of these patients shows that three are well at the present time and the other is at home in partial remission. The remaining patients concerning whom we have treatment and follow-up data had long and stormy hospital courses, often with frequent relapses but with good ultimate prognoses.

We have been able to follow twenty-eight patients for from one to eight years after their illnesses. Three of these (all schizophrenic) are still in hospitals and must be considered permanently mentally ill. Seven patients are able to be at home and to carry on a partially normal life, but are still having mild symptoms. The remaining eighteen patients recovered and have maintained their recovery to the present time (Table I).

The question of recurrence of mental illness in patients after having once had a puerperal psychosis is invariably asked by the patient and her family. Of the twenty-eight patients we have followed, only ten have had more children, and one of these had a second postpartum psychosis. Two additional patients have had subsequent psychotic reactions unrelated to pregnancy and both recovered.

Reviewing the entire reproductive history of the group, we find thirty-seven women who had two or more pregnancies. Of these, six have had postpartum psychoses on two occasions. Thus there appears to be about one chance in six of the disease reappearing in a subsequent pregnancy. Compared with the average incidence of once in 600 pregnancies, the chances of a postpartum psychosis are about 100 times greater in a woman who has been psychotic following an earlier pregnancy than they are in a woman without such a history. Obviously great caution must be taken in advising a patient about further children after she has had such an illness.

TABLE I. FINAL RESULTS
1 to 8 Year Follow-up

Type of Psychosis	Recovered	Improved (Home)	Unimproved (in Hospital)
Depression	8	2	
Manic	1		
Schizophrenic	7	3	2
Schizo-affective	2	1	1
Toxic		1	
Total	18	7	3

Conclusions

Puerperal psychoses are most likely to occur in women with family histories of mental illnesses and past histories of unstable personalities. The disease occurs most commonly following the first three pregnancies, but may not appear until after the sixth pregnancy. An uneventful pregnancy, with normal labor and the birth of a healthy child, is no protection against the development of puerperal psychosis. The clinical picture is that of any of the usual functional mental illnesses. The disease carries a distinct threat of suicide and of homicidal impulses against the newborn infant. The prognosis for recovery is good, usually after a prolonged and stormy hospital course. The chance of a recurrence in subsequent pregnancies is about one in six.

BENIGN STOMACH ULCERS

The actual incidence of benign ulcers of the greater curvature of the stomach may be much higher than the reported cases—despite statements that this benign type of ulcer is rare in comparison to malignant ulcers in similar location.

This is the suggestion of Dr. Frank S. Browne, radiologist from Wichita Falls, Texas, in the March issue of the *American Journal of Roentgenology, Radium Therapy and Nuclear Medicine.*

He reported a patient in whom most of the characteristics associated with carcinoma were present, yet microscopic examination revealed a benign peptic ulcer.

The ulcer itself had been discovered during an x-ray examination of the gastrointestinal tract.

"Verbal reports from numerous observers would indicate that the actual incidence of benign greater curvature ulcer is much higher than reported cases," concludes Dr. Browne.

Psychiatric Illness Following Gastric Resection

JOHN J. REGAN, M.D. and
CLARENCE J. ROWE, M.D.
Minneapolis, Minnesota

THE role of emotional factors in the etiology of peptic ulcer has been the subject of much theorizing and of some objective research. Investigators from the time of Beaumont have made observations on changes in gastric function under a variety of emotional stresses. Despite these observations the precise mechanism of ulcer production following stress has not been formulated. However, it seems to us that the studies of such investigators as Alexander,[1] Szasz,[4,5] and Mahl[3] suggest a basis for proper dynamic treatment of peptic ulcer patients and point the way toward research which can throw additional light on the problem.

TABLE I.

Patient	Age	Sex	Diagnosis	Indication for Surgery	Adjustment Prior to Resection
1	47	F	Psychophysiological gastro-intestinal reaction	Peptic ulcer	Inadequate
2	49	F	Drug addiction. Psychoneurotic reaction, mixed	Peptic ulcer	Poor
3	56	M	Depressive reaction	Peptic ulcer	Adequate but markedly hypochondriacal
4	37	F	Depressive reaction	Peptic ulcer	Adequate
5	54	M	Depressive reaction	Peptic ulcer	Nervous breakdown, age 40. Good recovery
6	38	M	Depressive reaction	Peptic ulcer	Adequate
7	57	M	Depressive reaction (psychotic)	Peptic ulcer	Adequate
8	41	M	Depressive reaction	Peptic ulcer	Poor
9	50	F	Paranoid state	Esophagitis	Adequate
10	59	F	Catatonic reaction	Esophagitis	Adequate

We are concerned here with ten patients who were seen on the wards of the University of Minnesota Hospitals for psychiatric treatment or consultation and who gave a history of previous gastrectomy. These are consecutive unselected cases collected during the past two years. So far as we can determine from a review of the literature, there is only one report which considers the results of this surgical procedure in terms of total social and emotional adjustment. That is, Browning and Houseworth's[2] study of sixty duodenal ulcer patients, thirty of whom were gastrectomized and thirty of whom were treated medically. The gastrectomized group showed a reduction of ulcer symptoms but a marked increase of psychosomatic and psychoneurotic symptoms. In the medically treated group the reduction of ulcer symptoms was less dramatic but there was no increase in psychosomatic or psychoneurotic symptomatology. In addition long term follow-up demonstrated an increase in psychogenic disturbances and organic difficulties in the post-gastrectomy group as compared to the non-gastrectomized group. In light of total ability to get along in the world, the thirty gastrectomized people were less well off than the thirty who were managed medically.

The ten patients we are reporting had gastrectomies by several surgeons in various hospitals from three days to nine years before we saw them (Table I). Of the total, eight patients had psychiatric difficulties which from history seemed clearly related to the gastric resection. Of the eight, six were depressive reactions, one was a catatonic reaction and one a paranoid reaction. The six depressive reactions occurred in patients who had gastrectomy for peptic ulcer. The catatonic reaction occurred in a woman who had a gastric resection for severe esophagitis and the paranoid reaction in a woman who had a gastric resection for esophageal obstruction. Two of the ten patients had emotional illness which was apparently unrelated to the gastrectomy. One of these (Case 2) had a history of longstanding, severe neurotic difficulty including dependence on drugs and the other (Case 1) was a Latvian refugee who had a history of intense,

Dr. Rowe is director, Hamm Memorial Psychiatric Clinic, Saint Paul, and clinical assistant professor, Department of Psychiatry, University of Minnesota.

early deprivation, plus repeated exposures to severe emotional trauma during the occupation of her homeland by hostile forces.

The Minnesota Multiphasic Personality Inventory was administered to nine of the patients. All profiles were abnormal. Six profiles showed patterns commonly found in people with depressive reactions, *i.e.,* primary elevations on the left side of the profile with the apex at D and a secondary elevation on the right side with the apex at Pt. Figure 1 shows the average profile of the depressed group. These profiles were on the patients who had gastric resections because of peptic ulcer and are no different from profiles of patients with depressive reactions unassociated with gastrectomy. Two of the profiles have in common a V configuration on the first three scales which is characteristic of neurosis with hysterical features (Fig. 2). These profiles occurred in the two cases (1 and 2) who had peptic ulcer, long histories of severe neurotic difficulties and in whom the psychiatric illness did not seem related to the gastrectomy. The profile of the patient who had a paranoid reaction was one which is usually considered psychotic. No profile was obtained on the patient who had the catatonic reaction.

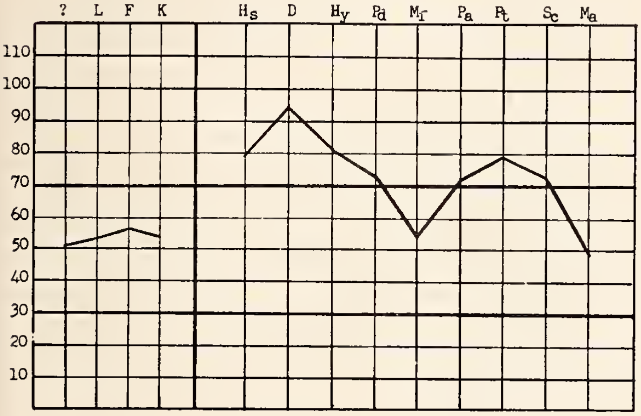

Fig. 1. Average MMPI profiles of the six cases with depressive reactions related to gastrectomy. (Cases 3-8, inclusive)

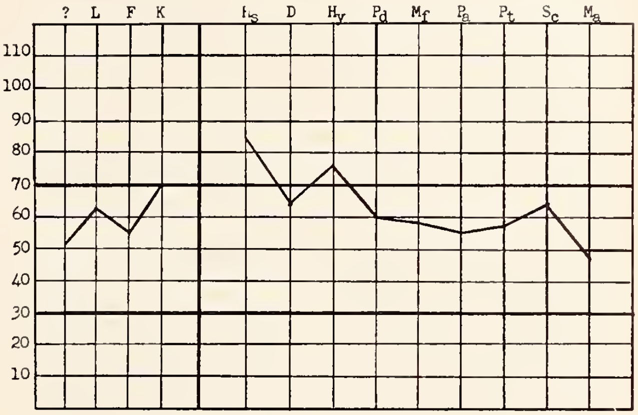

Fig. 2. Average MMPI profiles of the two cases in whom psychiatric illness was not related to gastrectomy.

Summary

We have reported ten patients who had psychiatric illness and gave a history of previous gastric resection. In eight of the cases, psychiatric illness seemed clearly related to the resection. Six of these were depressive reactions and occurred in patients who had resections for peptic ulcer. The two non-depressive psychotic reactions followed resections for conditions other than peptic ulcer. Two patients had psychiatric illness seemingly unrelated to gastrectomy.

Conclusions

1. It appears to us that gastric resection bears a psychiatric morbidity which is generally unrecognized and which to our knowledge has not been reported previously.

2. From this admittedly small group of cases, it seems that the psychiatric reaction to this surgical procedure is different in ulcer and nonulcer patients.

3. The evaluation of gastric resection, as well as other surgical procedures, in terms of subsequent emotional and social adjustment, is an area insufficiently investigated and deserving of further study.

Medico-Legal Relations

A Joint Report

GORDON R. KAMMAN, M.D., and
DAVID W. RAUDENBUSH, LL.B.
Saint Paul, Minnesota

At the request of President Wallace Ritchie, the attention of the Legislative Committee of the Ramsey County Medical Society during 1954 was directed to a study of medico-legal matters, especially those pertaining to expert opinions in personal injury suits.

The President of the Ramsey County Bar Association, Mr. Frank Hodgson, was asked to appoint a committee from the Bar Association to meet with the committee from the Ramsey County Medical Society, and during the summer a number of joint meetings were held.

The report of this Joint Committee is presented herewith.

THE Joint Committee on Medico-Legal Relations has held three evening meetings to discuss topics of common interest proposed by the medical members and lawyer members at separate meetings. In addition, the full committee has considered and agreed upon this joint report, which is based upon the minutes of the discussion meetings and partial drafts prepared by individual members.

The objective the committee has had in view is the improvement of working relations between practitioners of the medical and legal professions. Since those relations have their focus in the court room, most of the problems considered by the committee arise out of or are connected with the presentation of medical evidence to triers of fact. They commonly arise, however, long before trial —almost as soon as the attorney-client relationship is superimposed upon the physician-patient relationship; and they may last longer than the litigation. The difficulties may be of various kinds: questions of financial responsibility and of the loss or unproductive consumption of valuable professional time are more frequent sources of irritation or friction than actual or suspected misconduct.

The committee was both surprised and encouraged to discover that most of these interprofessional troubles are traceable in large measure to ignorance on the part of one profession of matters taken for granted by the other. The mutual education which resulted from this discovery was a valuable experience for all the committee members, and the committee is therefore hopeful that a wider audience may also find something helpful in this report of its deliberations.

Before summarizing the conclusions reached on the particular subjects discussed, it seems wise to restate certain fundamental principles which are known to and accepted by both professions. They form a common point of departure for the thinking of medical and legal practitioners with respect to many of the practical problems, and illuminate—or should illuminate—the solutions to be reached. We identified three such principles, as follows:

1. A trial of issues of fact, whether before a jury, judge or referee, is an essential step in the administration of justice in a civilized society.
2. The quality of the justice thus administered is directly dependent upon the degree of accuracy achieved, in the determination of fact issues.
3. In practice, medicine and law are both arts and reflect intuitive processes and other subjective elements. To the extent that this is unavoidable, the conclusions reached on medical questions are not and cannot be altogether objective—that is, susceptible of scientific proof.

It follows that the trial of issues of medical fact should have as its goal the attainment of as great a degree of objective certainty as possible, not only on the part of the medical witnesses, but also on the part of examining and cross-examining counsel. Mutual recognition and acceptance of the fact that absolute certainty is rarely attainable in

---

Report of Joint Committee on Medico-Legal Relations of the Ramsey County Medical Society and the Ramsey County Bar Association.

respect to cases which are brought to trial should encourage pre-trial education of lawyers by doctors. This in turn presupposes agreement as to the respective roles and obligations of attorney, client-patient and physician as to all matters connected with the impending trial. Is the physician expected to charge the time spent on such matters to the attorney, to the client-patient or not at all? Does it make any difference whether he is or has been the client's attending physician, or has been consulted for the purposes of the litigation only? Uncertainty or confusion as to how such questions should be answered often mark the beginning of misunderstanding, and so the committee took them up first, reaching the conclusions stated below.

Medical Fees

Attending or Consulting Physicians.—(For the purpose of this subject matter, these terms mean physicians or surgeons engaged for the purpose of care and treatment of the patient, as distinguished from a physician or surgeon engaged for the purpose of litigation.)

1. Expense of care and treatment is the obligation of the patient, irrespective of the litigation, or the outcome thereof.

2. Expense, if any, for preparation of medical reports for use by patient's counsel is the obligation of the patient.

3. Expense arising from court appearance is the obligation of the patient, irrespective of the outcome of the litigation. Counsel for the patient is under no legal obligation to pay such fees.

4. In the event of recovery, counsel have a moral obligation to use all reasonable measures to assure payment by the client of the statement for services of the attending or consulting physician, not only for the court appearance but also for services rendered. Whenever possible, unpaid statements should be satisfied as part of the process of distributing funds recovered in the litigation. Counsel unable to make arrangements for satisfaction of unpaid medical bills should promptly notify the doctor of such fact.

5. It is improper for the attending or consulting physician to insist, as a condition precedent to his testimony, that counsel guarantee payment of an unpaid bill for medical services, or bill for services to be incurred for the court appearance.

6. If, during the course of treatment, counsel believes that his client should receive further care or treatment from another physician, counsel should confer with the attending physician and in the event of disagreement make his recommendation to his client. Only with the approval of the attending physician or of the client should counsel engage the services of the second physician or consultant and then should make plain that the services, if undertaken, are to be at the expense of the client-patient.

Examining Physicians.—(For the purpose of this subject matter, this term means a physician or surgeon engaged for the purpose of litigation rather than for care and treatment.)

1. Expense of examination and report, as well as x-ray expense and similar costs necessary for a complete examination, are obligations in the first instance of counsel requesting the same. This fact does not relieve the client of his ultimate liability to pay the examining physician or reimburse his attorney.

2. Expense of court appearance is an obligation in the first instance of counsel requesting the same, but subject to the same comment as above.

3. It is proper and desirable practice that whenever an attorney refers a client to a physician for examination, he should do so in writing, stating the terms of the reference. If the attorney disclaims liability for the fee or if the physician doubts the attorney's credit, the physician may be justified in withholding his report until the fee is paid or in declining to testify until mutually satisfactory financial arrangements have been made.

4. It is improper for the physician and the attorney to enter into any arrangement making the payment of medical fees, or the amount thereof, contingent upon the outcome of the litigation. Fixed fees should be established prior to the examination or court appearance.

5. Payment of the examining physician's fees should be made promptly upon completion of his services. Delay in the final disposition, such as appellate procedure, is not sufficient reason for counsel to delay payment.

Medical Fees for Court Appearances.—

1. The fee to be charged by a medical witness for court appearance should be charged after

giving consideration to the following facts: (a) place of trial, (b) travel time involved in appearance, (c) actual time away from office, (d) cancelled appointments due to court appearance, (e) preparation required for testimony, (f) interference with daily schedule due to unforeseen and unavoidable delay, (g) duration of testimony, (h) nature of testimony, (i) ability to pay of party being charged for services.

Medico-Legal Aspects Before Trial

Physicians who undertake to treat an injured party must recognize an obligation to that patient to testify to the facts relating to the injuries; the care and treatment, and the duration of the pain or disabiliy. Attending physicians are not justified in declining to testify because of personal aversion to court rooms, dislike of patient or attorney, unpaid fees, or other personal reasons. The attending physician should realize that his appearance in court is not entirely a matter of discretion on his part. His appearance can be required by service of a subpoena and payment of ordinary witness fees, even though opinion evidence may be sought. Where a doctor has been so required to give an opinion, the Court in its discretion may allow the prevailing party in the law suit (if the doctor has testified in his behalf) to tax against the losing party expert witness fees for that doctor. In the State Courts the law allows the prevailing party to tax $25.00 a day or, in extraordinary cases, up to $50.00 a day in the discretion of the court. There is no such provision in the Federal Courts.

Conference before trial between the physician and attorney is essential to the proper presentation of medical testimony.

1. Physicians should willingly consent to such conference.

2. Professional courtesy should be afforded counsel in arranging the time and place of such meeting.

3. Sufficient time should be allotted to permit full discussion of the problem.

4. Counsel should acquaint the physician with any peculiarities of the law which may be encountered during the medical testimony.

5. The physician is entitled to compensation for time employed in such conferences. An attending or consulting physician may charge the patient; an examining physician, the attorney.

6. Similarly, an attending or consulting physician, on the one hand, or an examining physician, on the other, is entitled to charge the patient or the attorney, as the case may be, for the time necessarily spent in preparing a written report.

7. Counsel should acquaint their clients with the fact that they will be billed either directly by an attending or consulting physician or for reimbursement by the attorney for medical fees paid to physicians for services prior to the trial and for testimony upon the trial.

8. Counsel should extend every consideration to the doctor regarding the time at which he may be expected to appear in court. During the trial, lay testimony may be often harmlessly interrupted to allow a waiting medical witness to testify. Conversely, the doctor should extend every consideration to counsel in arranging for pre-trial conferences.

Histories and Examinations Before Trial

Histories.—

1. It is the privilege of an examining physician, even though the purpose of the examination is limited to qualifying the physician to present expert testimony, to inquire into the patient's history as fully as he deems necessary or desirable in order to arrive at an opinion concerning the patient's medical condition, even though some parts of the history may bear upon liability issues.

2. It is improper for an examining physician to record under the guise of history self-serving statements with respect to liability issues only, volunteered by the patient, or other items of history which the physician knows without further consideration to be irrelevant.

3. It is improper for an attorney to advise his client who is about to submit to an examination to refuse to disclose information within the scope of paragraph 1 or to volunteer statements within the scope of paragraph 2.

4. A patient or his attorney, with the patient's written authorization, may inspect all hospital records pertaining to the patient without the consent of the attending physician or hospital administrator. Such records may be removed, however, only by subpoena.

Examinations.—

1. It is inadvisable for an examining physician to solicit the opinion of an attending physician or even to consult with him except for the purpose of gaining essential information which cannot be obtained from other sources.

2. It is unnecessary and undesirable for an examining physician acting for the opposing side to express any opinion to the party being examined.

3. Findings of the examining physician should be imparted only to the person or party for whom the examination was made.

4. Joint examinations with other physicians expected to be called as witnesses by either side of a litigation tend to impair independent thinking and judgment and are therefore to be avoided except under unusual circumstances.

5. An attorney should not be present at an examination of his client.

6. An attending or examining physician should not express to the patient-client any opinion as to the settlement value of his law suit, nor should he express any opinion as to the effect of the litigation upon the patient-client's health unless he has first talked to the attorney and has ascertained that the attorney has failed or neglected to communicate the opinion to the client-patient.

The Medical Witness in Court

Production of Records.—

1. Medical witnesses are entitled to have the courage of their honest convictions and steadfastly to hold to a well-founded opinion based on sound medical principles. But dogmatic positions and attitudes are not ordinarily well founded, especially in a case in which reputable physicians are prepared to express contrary opinions, and are thus out of harmony with the basic purposes of the trial. Under no circumstance is a medical witness to regard himself as an advocate, or be encouraged to assume such a role by the attorney who has arranged for his testimony.

2. It is not only the privilege but the duty of counsel for the opposite side to explore the foundations of a medical opinion and to expose any weaknesses which may appear either in the basis or content of such an opinion. Provided that the technique employed by the cross-examining attorney is not unjust or ungentlemanly, the witness should not assume an antagonistic attitude. He should recall that in all probability the cross-examination reflects a contrary medical interpretation of the objective facts. An obstinate refusal to recognize the justifiable possibility of a contrary view does not advance the cause of justice. If the witness is "resolving a doubt" in favor of the party calling him, he should candidly admit that he is doing so.

3. Simplicity of expression is the finest attribute of a medical witness as well as of other witnesses. If technical language must be used, its meaning should be explained in lay terms sufficiently so that not only the judge and the attorneys but also the jurors may reasonably be expected to understand it.

The Redress of Grievances

The County and State organizations of each profession maintain standing committees for the hearing of complaints of professional misconduct, but the details are not widely known outside the membership of the respective professions. It seems desirable, therefore, to include a description of these committees as a part of this report.

Ramsey County Society and Minnesota State Medical Association

1. *Grievance Committee.*—This is a committee of five appointed by the President of the Ramsey County Medical Society. It does not hold regular sessions but meets on call whenever the need arises. The duties of the committee are to hear and investigate complaints concerning the professional conduct and ethical deportment of individual physicians and to attempt amicable adjustment. The committee hears complaints from any source: other physicians, organizations or members of the general public. All complaints must be in writing.

2. *Medical Defense Committee.*—This also is a committee of the County Society but is relatively inactive, its duties having been taken over by the State Committee on Malpractice Insurance.

3. *Committee on Malpractice Insurance.*—This is the organ of the State Medical Association which examines complaints in malpractice cases brought against members of the State Medical Association. The committee furnishes forms to

be filled out by the defendant physician in such cases and makes recommendations after the information called for has been compiled and evaluated. The state association also stands ready to provide expert testimony in a malpractice case against one of its members.

4. *Committee on Medical Testimony.*—This also is a committee of the State Association. It handles complaints against doctors appearing as expert witnesses received from other doctors, judges, lawyers and other interested parties. The committee concerns itself with the evaluation of the sworn testimony given by the doctor complained against. It calls in for assistance experts from relevant specialties who examine the testimony and make findings as to whether or not it was justifiable or at least honest. If the findings are that the witness was not acting in good faith or that his testimony was dishonest or if there was any other form of unethical conduct on his part, the committee then recommends to the State Board of Medical Examiners disciplinary action.

Ramsey County and Minnesota State Bar Associations

1. *Ethics Committee.*—This is a committee of the County Association whose functions parallel those of the Grievance Committee of the County Medical Society described in A-1 above. This committee has no disciplinary powers other than the power to recommend expulsion of an erring lawyer from membership in the County Bar Association, and therefore its most frequent recourse is to refer complaints found by it to be meritorious to the State Board of Law Examiners.

2. *State Board of Law Examiners.*—As its name implies, this is not an organ of the Bar Association but an official body. It is mentioned in this context because of the direct reference to it of complaints heard by the Ethics Committee of the County Bar Association, as stated above. The State Board conducts an independent investigation and if it finds probable cause to believe the complaint well founded, it files charges against the respondent attorney with the Supreme Court of Minnesota. The Supreme Court refers the matter to a District Judge, who hears sworn testimony and receives evidence as a referee and makes written findings of fact but no recommendations. The case is then briefed and argued before the Supreme Court on the record made before the referee, including his findings, and the Supreme Court, by written opinion, then determines what, if any, punishment shall be meted out.

3. *Practice of Law Committee.*—This committee of nine members of the State Bar Association is charged with the duty to investigate cases of unethical conduct, including the disbarment and reinstatement proceedings affecting members of the Bar. The by-laws require it "to take such action with respect to the matters investigated as may be directed by the Board of Governors or Supreme Court of Minnesota." The 1954 report of this committee indicates that it has been largely, if not exclusively, engaged in conducting correspondence with reference to grievances against attorneys by their clients. Grievances originating in St. Paul or Ramsey County presumably would be referred by the State Committee to the Ethics Committee of the County Association, rather than processed directly.

Members of the Ramsey County Medical Society Committee were: Drs. E. M. Hammes, Jr., D. L. McCain, B. I. Derauf, H. R. Tregilgas, and Gordon R. Kamman, Chairman.

Members of the Ramsey County Bar Association were: Russell Carlson, Linus Hammond, Lawrence Hazen, Charles Murnane, and David W. Raudenbush, Chairman.

DISEASES OF THE CHEST

Cancer of the lung, industrial lung disease, chronic bronchitis and emphysema going on to pulmonary heart disease, bronchiectasis and the like are, admittedly, less of a social scourge than pulmonary tuberculosis but they also bring in their train social and economic as well as medical problems. Moreover, the advances of thoracic surgery . . . make the inclusion of all chest diseases an economic proposition for the re-orientated chest service of the future. Tuberculosis will continue to lay first claim on our attention for many years ahead.—PHILIP ELLMAN, M.D., *Journal of Royal Institute of Public Health and Hygiene,* August, 1954.

Cholangiography

A Simplified Technique

G. M. A. FORTIER, M.D.
Little Falls, Minnesota

THE PROBLEM of cholangiography, apart from its controversial aspect, has lent itself to many modifications. Each of these proposes either refinement or increased rapidity of technique, besides excellence of plate exposure; having as an end in view better diagnostic results.

The present article deals with only another practice of preparation for injecting the dye into the common duct. The procedure is offered because it is felt to be an improved, simplified method of operating room cholangiography. To be worthwhile it should properly offer increased rapidity over previously suggested methods, besides adding to the lessening of delay in the operation as a whole while the plate is being developed and interpreted. For the sake of comparison a review of the following methods is made:

Behrend clamps the cystic duct near the gall bladder, then injects the dye directly into that duct through a needle.[1]

Best places dye directly into the common duct through a needle.[2]

Bettman threads a ureteral catheter through the cystic duct, then ligates *to prevent backflow.*[3]

Carter and Gillette inject into the cystic duct, after ligating near the gall bladder. They also attempt to fill the gall bladder with dye under pressure, thereby forcing the media into the common duct.[4]

Caylor, after transecting the cystic duct, threads a ureteral catheter into the common duct, then doubly ligates the cystic duct to prevent backflow.[5]

Hagen and Townsend also pass a ureteral catheter through the cystic duct followed by ligation of that tube.[6]

Hicken inserts a large needle into the gall bladder. After aspirating that organ he distends it with dye through the same needle, forcing the media into the common duct.[7]

Loundsbury, et al, pass a ureteral catheter through the opened end of the cystic duct followed by ligation.[8]

Mehn places a catheter in the opened cystic duct, then ligates.[9]

Mirrizi employs a small cannula fitted with an attached bulb *to prevent backflow.* This he inserts into the open end of the cystic duct.[10]

Robins ligates the cystic duct before injecting the dye into it through a needle.[11]

In the preceding methods certain factors emerge: all of them are practiced in the erroneous belief that dye injected into the common duct under pressure will flow freely back into the gall bladder. Those methods dealing with cystic duct injection are practiced for the most part after the gall bladder has been removed, resulting in a period of inaction while the plate is being developed. Techniques which distend the gall bladder with dye must face a certain percentage of failures due to the imposition of the gall-bladder shadow on that of the common duct. *None is likely to be practiced in the presence of acute cholecystitis.*

The proposed approach to the problem apparently obviates the above mentioned objections. In all the cases studied there has not occurred any but minimal backflow of dye into the gall bladder, even though large cystic ducts have not been ligated. The maneuver is practiced before cholecystectomy is begun. That operation is performed during the waiting period necessary for development and interpretation of the x-ray plate. *The procedure may be carried out in the presence of acute cholecystitis if the ampullary region of the gall bladder is at all approachable.* If there is the least doubt regarding the absence of calculi in the common duct, exploratory choledochotomy is performed. It is in those cases only in which the presenting findings and history definitely assure the absence of calculi that the study is made, except as noted at the close of the article. Small common ducts are not studied.

Technique

A cannula of the type illustrated is employed. It is a Wright sinus cannula. It measures about 5.5 inches in length. The diameter of the bore is about one millimeter, and the tube diameter two millimeters. The end is fitted and ground to receive a standard syringe hub.

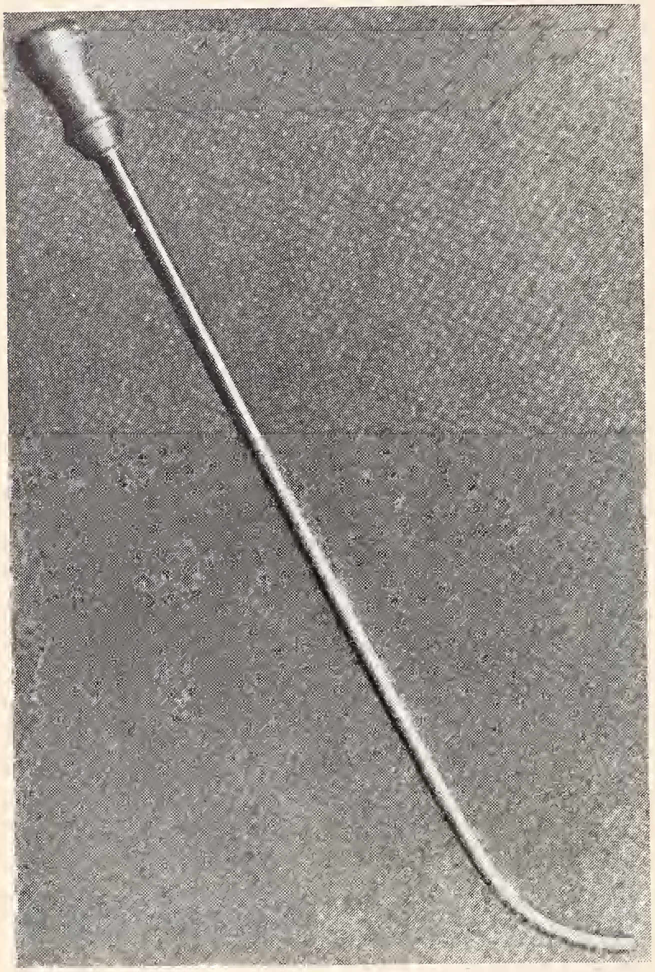

Fig. 1.

Following examination of the field and aspiration of the gall bladder, in necessary cases, one exposes the area of the ampulla. At a point where one usually applies a clamp in this area a small nick or scissor wound is made through the wall. The cannula is inserted into this opening and guided into the common duct by way of the cystic duct. This procedure should be carried out gently, no force being used. Resistance offered by the valves of Heister is not always present, but if so one gently jiggles and maneuvers the instrument, and very little difficulty is encountered, even in small cystic ducts. Proof of the cannula's entry into the common duct is easily verified. In most cases the tip can be observed, as it is rotated, slightly tenting the wall of the duct. In the presence of doubt, aspiration of bile proves the point. The one misfortune which might occur is a mal-direction resulting in the admission of the cannula into the submucosal layer of the cystic duct. Such an occurrence is disproven by the aspiration of bile. Gauze is gently packed about the tube and gall bladder, and, the x-ray unit being in readiness, the dye is injected. *No blocking of the cystic duct is required.* On no occasion has any backflow of dye been observed on the x-ray plate, except in minimal amounts.

Following exposure the cannula is removed, the opening clamped, and the cholecystectomy begun. This procedure is well progressed or finished by the time the x-ray plates are developed and returned to surgery for study. The time lost, therefore, is minimal as the procedure becomes an active part of the whole operation rather than being a disconnected interposition necessitating an inactive waiting period, as would be true of injection of the common duct with dye followed by x-raying after the gall bladder had been removed.

This simple method is employed also, on occasion, on two other types of cases. When several calculi are known to be present in the common duct at least the minimal number is learned, allowing the enjoyment of that little extra security such knowledge offers. In the case of acute cholecystitis when edema is of such extent as to invite disaster if the common duct is sought for, the assurance that the stones are present in the common duct might, in a particular case, influence one's decisions at the operating table as well as during the postoperative period.

The above outlined procedure has been employed in seventy-five cases. In no instance has any immediate or delayed harm been apparent. In no case was there any suggestion that the procedure affected in any degree the postoperative morbidity. There were no cases of pancreatitis. The criteria for considering the common duct to be free of calculi were narrowly limited. The results, therefore, of the seventy-five case studies were negative. The postoperative follow-up studies over a period of four years produced no instance of presence of overlooked calculi.

Choking Accidents

LAWRENCE R. BOIES, M.D.
Minneapolis, Minnesota

THE ACTUAL incidence of choking accidents is difficult to estimate, but these experiences in some form are very common. Few persons pass through childhood without experiencing at least a mildly disturbing episode of having had a particle of food "go the wrong way." In an occasional instance such an episode has serious possibilities. Newspaper references to asphyxia occurring while eating are not rare. When death occurs from the immediate effect of a foreign body lodging in the air passages, the site of this obstruction is usually in the larynx. More often than not a foreign body entering the air way is coughed up. Those that cannot be coughed up are usually found in a bronchus where a varying degree of morbidity occurs, depending on the size and type of the substance and the duration of its stay in the lung.

Etiology

In order of importance and frequency the following causes for choking accidents can be listed:

1. *Hurried eating.*—That often means inadequate mastication or chewing of food. In the edentulous who wear false teeth, chewing tends to be less thorough, or if attempts are made to chew without any teeth, the process of mastication is negligible except for very soft foods. Likewise, the infant can only grind up food to the extent of his teeth, and when he puts such a substance as a peanut in his mouth he has no molars to grind up this type of food.

2. *Lack of concentration on the business of eating, particularly among small children.*—Among adults, conversation is part of the pleasure of a dinner party and leads to leisurely eating, which should insure proper mastication. With the small child, distraction of his attention from the business of eating may be another matter. The child who so often may gluttonously shove food into his mouth is liable to the hazard of getting the food the wrong way if his attention is distracted by other children, or he attempts to play as he eats. Boisterous play among children at a dinner table is an excellent setting for a choking accident.

3. *Allowing a small infant to play or crawl where there are small objects within reach that he could put in his mouth.*—He will follow his natural instincts, which means that anything he picks up will be put in his mouth, if there is room. Pins of various types, nutmeats, popcorn kernels, beads, buttons, eggshells, pieces of wood, parts of toy instruments et cetera, have all been removed from the trachea or bronchi of small infants.

4. *Holding objects in the mouth.*—Professionally there is the seamstress who holds pins in her mouth, or the carpet layer with a mouth full of tacks or the carpenter with his nails. Since these are adults and their minds are usually on their work, choking accidents are uncommon. Also, there is a greater tendency for the foreign body to be swallowed than for it to go into the airway because the co-ordination of the swallowing mechanism and the laryngeal function is better developed in the adult. However, the size and shape of the type of foreign body mentioned precludes much of a possibility of actual asphyxia with an accident from this cause.

5. *Injury to the larynx from external trauma.*—A blow across the external surface of the larynx, particularly if localized at the prominence of the "Adams Apple" can cause enough progressive soft tissue swelling within the larynx to seriously embarrass the airway. Whenever there is loss of voice following external injury to the laryngeal area, or any complaint of difficulty in breathing, careful and continuous observation for the development of serious respiratory distress is in order.

Since this discussion is concerned only with accidents, other causes of choking have not been considered. Inflammatory diseases of the larynx plus the occasional case of edema from allergic reaction and tumors outrank in incidence foreign bodies as a cause of asphyxia, even though serious inflammatory lesions are less common than they were prior to the advent of the sulfonamides in

1937 and the antibiotics in 1942. In addition, the management of these cases from the standpoint of skill in early diagnosis and supportive care has improved.

Management

The immediate management of a choking accident is usually in the hands of a layman. A time-honored practice which the average adult follows is to turn the child "bottom side up" and slap him on the back of his chest. Presumably this maneuver is followed to utilize the force of gravity while the slap or pounding on the back of the chest may serve both to dislodge the foreign substance and aggravate the cough reflex. It seems to work in a fair percentage of cases and it seems logical. The only possible hazard in this would be in the instance where a foreign body had already passed through the glottis and is in the trachea or a bronchus, and that it might become lodged in the glottis as it came back when the patient was tipped "bottom side up."

Another maneuver that has some merit is to incite gagging so as to cause vomiting by "sticking a finger down the throat." This would be most effective in a situation where a foreign body is lodged at the introitus to the esophagus and in this position presses on the larynx to partially embarrass respiration.

When these measures do not bring relief, the hazard is often extremely serious and calls for action that the layman is not equipped to provide. The obstruction is usually at the glottis with impending asphyxia. Occasionally, the site of obstruction may be lower within the trachea from a foreign body lodged at the carina and partially obstructing both bronchi. In the latter event asphyxia is not as rapid.

Only tracheotomy will relieve complete glottic obstruction, and it has been only in extremely rare instances that a layman has had the knowledge of what to do. If a physician can be reached in time, he may have to act without adequate tools. Tracheotomies have been done with a jackknife. This discussion was not intended to cover the details of surgical technique of tracheotomy but the following general maneuvers can appropriately be outlined.

In the case of a small child the operator may find it helpful to be seated, if that is possible, with the child on his back across the operator's knees and with the head somewhat extended. The right-hand operator then palpates the site of incision with the index finger of the left hand, starting first with the prominence of the thyroid ("Adam's Apple") and then feeling the flat surface of the membrane between the firm surface of the thyroid cartilage and the rounded hardness of the cricoid ring below. The trachea begins below this ring. This same left index finger and thumb then act to spread tense the soft tissue over the trachea as a knife in the right hand makes a midline incision and with succeeding strokes bares some trachea. The isthmus of the thyroid is the most vascular structure encountered. If it can be displaced that is desirable, but because of the urgency of the situation a direct incision through it may be necessary. The trachea is next opened by a vertical slit through at least two rings or a horizontal slit through membrane below the first ring, and the margins of the slit are spread by any available means with an instrument or object small enough to keep the edges pried apart.

A more accessible site in certain instances for opening into the trachea below the level of the glottis is through the membrane between the thyroid cartilage and the cricoid ring (crico-thyroid membrane). A transverse slit through this membrane can be made usually without the necessity of transversing any very vascular tissue. Then after an airway has been established and the patient resuscitated, an orderly tracheotomy can be performed and the first incision repaired.

Prevention

The means of preventing choking accidents have already been suggested. These may be summarized as follows:

1. Avoid hurried eating and incomplete mastication of food.

In children this is most important. The business of eating should be their sole activity at the time. When mixed with play or boisterous conduct, a mouthful of food may easily go the wrong way.

Do not feed nuts in any form, or cookies containing nuts, hard candy, popcorn or firm pieces of fruit to infants. Be sure that any seeds are removed from oranges, et cetera.

2. Do not allow infants to play on a surface where there may be any small toys or objects within reach or a floor that is not clean of pins, toothpicks, hard food substances, seeds, et cetera.

3. The mouth should not be a temporary receptacle for pins, tacks, nails, et cetera. Special care should be observed on a farm so that small children do not put shelled corn or other seed materials in the mouth.

4. When the neck has been injured from a blow received in the area of the larynx, close observation is important if the voice is at all impaired.

Seminar

MULTIPLE SCLEROSIS

Diagnosis, Diagnostic Errors and Treatment

Z. R. MILLER, M.D.
Saint Paul, Minnesota

ALTHOUGH multiple sclerosis was described more than a century ago, it remains one of modern medicine's baffling maladies. The etiology remains unknown, the prognosis uncertain, and the treatment unsatisfactory. Though at first considered to be a medical curiosity, it is now estimated to afflict approximately 250,000 individuals in the United States. The neurologic disorder the illness produces is exceedingly variable. Only a small percentage of cases are of the classical clear-cut variety, consisting of ataxia, muscle weakness, nystagmus, diplopia, impaired visual acuity, intention tremor, scanning speech, and euphoria. These textbook cases can be readily diagnosed by the medical student; however, there are a certain number of cases that cannot be properly diagnosed by the astute neurologic consultant, especially during the patient's first attack. The cautious clinician will in such instances make the diagnosis of multiple sclerosis on an exclusion basis. To date, no fresh information can be supplied to help in the establishment of the diagnosis of this demyelinating disease. Nevertheless it is conceivable that with the newer biochemical techniques being utilized in the research laboratories, the questions regarding the etiology, diagnosis, and treatment of multiple sclerosis will be firmly answered in the near future. Until such answers are supplied, renewed emphasis on the establishment of the clinical diagnosis is warranted.

The "pathologic unit" in multiple sclerosis consists of a circumscribed area of nervous tissue in which primarily the myelin sheaths of nerve fibers are damaged with resultant transitory or permanent axone damage. If complete destruction takes place, there results sclerotic, gliotic plaque formation.

Typically, the pathologic foci are multiple and spread in scattered fashion throughout the white matter of the nervous system. The neurologic symptoms, transient or permanent, depend on the regions of the nervous system involved, the intensity of the demyelinization, and subsequent axone impairment. Usually, a new plaque gives rise to maximal dysfunction within forty-eight hours, followed by a moderately semi-stable period of several weeks and then a gradual improvement. The degree of improvement parallels the myelin reformation and intactness of the nerve fibers.

What produces this neurologic disorder? The early pathologists believed that glial overgrowth was the prime factor, hence the term sclerosis. The disease has been attributed in the past to various infectious agents including spirochaetes and viruses; but no positive evidence has ever been produced. More recent theories ascribe the demyelinization to circulatory abnormalities including venular thrombosis, altered coagulability and sludging of blood; to myelin-splitting ferments; to hyperergic reactions; to altered fat metabolism; or to some unknown toxin. It is most probable that many of the newer theories are linked in some way producing a chain of biochemical events; and it remains to be determined which are the prime factors. We need to know more about the nature of myelin. Isotopic tracer substances, enzyme, and lipid studies are being investigated to give added information about myelin metabolism.

Diagnosis

The major criteria for diagnosis of multiple sclerosis are wholly clinical. To this date no reliable positive laboratory test is available. The diagnostic clues are present in the manner in which the neurologic disorder is produced. The vast majority of cases occur in the first half of adulthood. Rarely does the initial attack occur in an individual before the age of twenty or over forty. Although there is no consistent pattern, the history of remissions and exacerbations with

---

From the Neurology Section, Veterans Administration Hospital and University Hospitals, Minneapolis, Minnesota.

gradual increasing neurologic disability is an important criterion. Another major criterion concerns evidence of multiplicity of neuropathologic lesions, based on neurologic signs, that unequivocally require scattered or disseminated foci. Thus it must be demonstrated that multiple sclerosis typically is a neurologic entity scattered both as to time and place. Nevertheless clinicians have seen and will continue to see cases that lack these criteria; for example, the steady progressive variety, the acute fulminating variety, and the single focal variety. The disease may begin with a single symptom of transient duration, as visual blurring, diplopia, weakness or awkwardness of limb, or numbness, to be followed by an interval of well-being for weeks, months or years before the onset of a second attack. Oftentimes the middle-aged adult during an acute attack will have forgotten an original bout of neurologic dysfunction unless specific inquiry is made. The spinal form of multiple sclerosis may reveal only a steadily progressive spastic paraparesis. Rarely an explosive fulminating variety with wide dissemination of lesions may initiate the onset and result in early death. As the diagnosis of multiple sclerosis usually carries with it a grave prognosis, each case warrents critical evaluation and especially so the atypical cases that do not fit in the "time and place formula." A diagnosis of multiple sclerosis made on the basis of a single focal sign, for example diplopia, must remain presumptive pending the subsequent development of neurologic signs of dysfunction.

The demyelinating process of multiple sclerosis has a predilection for certain areas of the nervous system; chiefly the posterior and lateral columns of the spinal cord, the cerebellar pathways, the medial longitudinal fasciculus, and the optic nerves. When all or most of these areas of the nervous system have been involved as a result of recurrent attacks, the diagnosis of multiple sclerosis is not difficult.

When considering the differential diagnosis, it is helpful to subdivide multiple sclerosis into various clinical types, depending on the major site of neurologic dysfunction. Thus we may have either a predominant cerebral, cerebellar, brain stem, cranial nerve (chiefly ocular), or spinal clinical subtype, or combinations thereof. Brain tumors, encephalitis, and subdural hematomas are to be differentiated from the cerebral variety; myasthenia gravis, carotid artery aneurysms, pineal, sellar and parasellar tumors from the ocular nerve form; acoustic neuromas, cerebellar tumors, pontine gliomas from the brain stem and cerebellar form; subacute combined degeneration, Friedreich's ataxia, amyotrophic lateral sclerosis, platybasia, cord tumors, and midline cervical discs from the spinal subtype of multiple sclerosis.

Various laboratory tests and procedures are utilized to give additional aid in differentiating a suspected case of multiple sclerosis from a host of neurologic disorders. The most commonly performed laboratory test is the lumbar puncture for examination of the spinal fluid. Even though in a small percentage of cases the cell count and spinal fluid protein are elevated, marked increases of either one or both strongly indicates that the disease is not multiple sclerosis. In no more than one-fourth of the cases does the characteristic first zone colloidal gold curve appear, and then usually occurring in the typical easily diagnosed cases. All cases with pure spinal signs require the Queckenstedt jugular compression test to rule out a spinal fluid block. It can be stated that a completely normal spinal fluid examination tends to enhance the diagnosis of multiple sclerosis rather than the reverse. Although various biochemical tests have been performed in the research laboratories on the spinal fluid and blood of patients with known multiple sclerosis, there still does not exist a practical test that will establish the diagnosis with the certainty present for diagnosing central nervous system syphilis.

Further specialized tests, including skull and spine x-rays, electroencephalography, myelography, angiography, and air encephalography are performed when indicated to rule out space-occupying lesions, which by the nature of their location might suggest multiple sclerosis. Myelography is a strongly recommended procedure in virtually all multiple sclerosis "suspect" cases that do not have findings or symptoms above the cervical cord level.

The greatest danger that can befall a patient with neurologic dysfunction is to be diagnosed and treated as having multiple sclerosis, when in actuality myasthenia gravis, chronic subdural hemotoma, benign spinal cord or brain tumor, or other specifically treatable neurologic entities exist. In the workup of the patient the clinician should pursue to uncover a specifically treatable disease if reasonably present in the differential diagnosis. As an illustration the patient with a combined degeneration syndrome (posterior and lateral tracts of spinal cord involved) may therefore require examination of the blood and urine, including studies for heavy metals (lead, arsenic, and mercury), gastric analysis, bone marrow; and in the event all these tests are normal, spinal fluid analysis, x-rays of the spine, and myelography which includes the entire cervical region are in order before labeling this patient as having the spinal form of multiple sclerosis.

Out of the many cases of multiple sclerosis seen, diagnosed, and treated at the neurologic service of the Minneapolis Veterans Administration Hospital from 1945-1955, the following cases are presented to demonstrate the need for constant surveillance and re-evaluation of all patients labelled with the diagnosis of multiple sclerosis. Furthermore these cases, all proven not to be multiple sclerotics, should caution all clinicians who treat neurologic patients, to be wary of all apparent multiple sclerotic cases that are not of the classical Charcot variety.

Case 1.—J. L. B., aged forty-three, was first admitted to Minneapolis VA Hospital, June, 1945, with the complaint of double vision followed shortly thereafter by weakness and impaired control of his lower extremities. During this period of hospitalization his diplopia improved only to return following an upper respiratory infection. His gait also deteriorated and it was noted that there was mild speech impairment with perioral weakness.

Positive neurologic findings included ptosis of the right upper eyelid, paresis of the right superior and lateral rectus, unsteady gait, absent abdominal and cremasteric reflexes, and symmetrically hypoactive deep tendon reflexes. Spinal fluid examination was entirely normal. A diagnosis of multiple sclerosis was made and patient was discharged much improved September, 1945.

The patient was readmitted to the Minneapolis VA Hospital on October 18, 1948, as a multiple sclerotic in an acute exacerbation. Two weeks prior to admission diplopia appeared on right lateral gaze with progression of diplopia in all fields of vision. He also noted progressive paresis of his arms, hands, and legs with a tendency for his ankles to buckle.

The significant positive neurologic signs on this admission included paresis of the right superior and internal rectus and of the left internal and inferior rectus, a right ptosis, and a mild to moderate generalized muscle weakness of the extremities which became more manifest on exercise. There were no positive pyramidal, posterior or spinothalamic column involvement. The previous diagnosis of multiple sclerosis was questioned in view of the age of onset and the chief neurologic signs of muscular paresis. A diagnosis of myasthenia gravis was considered and established following a presumptive prostigmine test. Twenty minutes after receiving 1 mg. of prostigmine with 1/150 gr. of atropine sulfate there was profound improvement of muscle strength with disappearance of the right ptosis.

Summary.—A forty-three-year-old veteran was first diagnosed as multiple sclerosis and treated for this disease until myasthenia gravis was firmly established three years later.

Case 2.—T. O. G., aged fifty-three, was first admitted to Minneapolis VA Hospital April 20, 1950, with a long history of gait impairment, incoordination of extremities, visual blurring, slurred speech, and intermittent headaches. More recently, he had had increasing difficulty with his right extremities, and the headaches which were previously considered to be of mild intensity became severe. A month prior to admission he had had two unconscious episodes, one lasting approximately five hours. A diagnosis of multiple sclerosis was first made on this individual in 1941 at a neurologic center and he carried that diagnosis ever since although seen and examined by many physicians at various clinics over a nine-year period.

On neurologic examination, it was noted that the patient was disoriented and confused. There was marked cranial nerve involvement including a bilateral three to four diopter papilledema, a right lateral rectus paresis, severe nystagmus in all directions being most severe on left lateral gaze, hypalgesia of the right side of the face with a decreased right corneal reflex, a right peripheral facial paresis, and a right nerve deafness. Other positive neurologic findings included ataxia of all extremities with intention tremors of the arms, worse on the right, hypalgesia of the left side of the body, bilateral positive Babinski, and bilateral ankle clonus and a mild nuchal rigidity.

Information received from a hospital where he was previously examined revealed a spinal fluid protein in excess of 200 mg. per cent. Significant laboratory data performed at this admission revealed pressure erosion of the sella turcica on skull x-rays and a diffusely abnormal electroencephalogram. A diagnosis of a right cerebello-pontine angle tumor was tentatively made, and a right suboccipital craniotomy was performed several days after admission revealing a large acoustic neuroma. There was a stormy postoperative course with resultant neurologic disability.

Summary.—A fifty-three-year-old veteran who had carried a diagnosis of multiple sclerosis for nine years to explain what was considered to be scattered neurologic signs and symptoms and without the characteristic history of exacerbations and remissions. There was progressive neurologic disability with the later development of signs of increased intracranial pressure which being present on his first admission to the Minneapolis VA Hospital indicated a brain tumor diagnosis and at surgery a right acoustic neuroma was removed.

Case 3.—R. B. H., aged twenty-four, was first admitted to Minneapolis VA Hospital December 9, 1947, on transfer from the VA Hospital, Fargo, North Dakota, with a differential diagnosis of chronic encephalitis and brain tumor. History included an episode of diplopia of two weeks' duration in November, 1943. In December, 1944, while in the Southwest Pacific, he noted blurring of vision and shortly thereafter developed diplopia and bilateral ptosis. The ptosis improved but the diplopia persisted to the present time. In November, 1945, he developed a coarse tremor of the right hand and arm and a month later noted numbness and awkwardness in this arm and hand which later spread to the right leg. Six months prior to admission, his speech was somewhat slurred and dysarthric, and he was unable to walk for two months preceding admission.

Neurologic examination revealed questionable temporal pallor of the optic discs bilaterally. There was a moderate bilateral ptosis with severe impairment of conjugate gaze and paralysis of upward and downward gaze and bilateral lateral rectus paresis. The eyes at times would move independently of one another. The pupils were small and fixed and did not react to light and accommodation. There was hypalgesia of the right side of the face with a reduced right corneal reflex. The motor system revealed a moderate hemiparesis of the right side with right hyperreflexia. Co-ordination tests were poor in all four extremities. Sensory examination disclosed impairment of all modalities on the entire right side. Mentally the patient appeared somewhat dull and there was a mild memory deficit for recent events.

From a neurologic standpoint a diagnosis of multiple sclerosis was made in view of scattered multiple lesions with suspected involvement of the mid brain, medulla, spinal cord and cerebral hemispheres. Included in the differential was a brain stem tumor. Laboratory data included a normal spinal fluid examination in all respects and a normal skull x-ray. A pneumoencephalogram was recommended to rule out a brain tumor diagnosis, and it disclosed a mild generalized dilatation of the ventricular system with normal or slightly enlarged subarachnoid spaces and basal cisterns, which indicated a degenerative process. Special serologic studies were negative for antibodies against eastern and western equine encephalitis. Patient was discharged on January 7, 1948, with a diagnosis of multiple sclerosis.

The patient expired at another hospital early in 1949, and an autopsy revealed an infiltrating pinealoma.

Summary.—A twenty-four-year-old veteran with a history of remissions and exacerbations with resultant progressive neurologic disability over a five-year period was diagnosed as having multiple sclerosis in view of multiple neurologic findings and a negative spinal fluid and pneumoencephalographic study. Post-mortem examination revealed an infiltrating pinealoma with severe involvement of his brain stem.

Case 4.—B. F. S., aged twenty-six, was first admitted to Minneapolis VA Hospital December 18, 1947. This patient carried a service-connected diagnosis of multiple sclerosis, previously diagnosed as post traumatic psychoneurosis. The patient gave a history of loss of control of his left leg with mild exacerbations and remissions over a four and a half year period. Patient first noted this disability shortly after bomb explosion during combat duty in 1943. He was examined at various service hospitals for this complaint. In spite of temporary remissions there was progressive impairment of his left leg, and in the fall of 1946 he was unable to work because of difficulty in ambulation.

Neurologic examination disclosed a spastic paresis of his left lower extremity, hyperreflexia of the lower extremities including bilateral ankle and knee clonus and bilateral positive toe signs and absent superficial abdominal reflexes. The pyramidal tract signs were more marked on the left. There was impaired superficial sensation in an area from T-2 to T-12. Positive laboratory data included a spinal fluid protein of 244 mg. per cent and a positive jugular compression test. Spinogram disclosed a block suggestive of an extramedullary lesion at T-1, and on laminectomy a neurofibroma was removed from the left C-8 nerve root.

Summary.—A twenty-six-year-old veteran who was previously diagnosed as having post traumatic psychoneurosis and later changed to multiple sclerosis was proven to have a neurofibroma of the cervical spinal cord four and a half years after his original symptoms.

Case 5.—A. F. P., aged twenty-three, was first admitted to Minneapolis VA Hospital December 30, 1946, with the complaint of awkwardness and impaired feeling in his right hand and arm. Objects would drop from his right hand. On examination there was mild weakness of his right hand and arm with an intention tremor. There was impairment of position, vibratory and discrimination sense in the right hand with no objective superficial sensory impairment. The deep tendon reflexes were definitely increased in the right upper extremity and suggestively increased in the right lower extremity with an equivocal Babinski sign. Spinal fluid examination was negative including the jugular compression test except for a spinal fluid protein of 60 mg. per cent. X-rays of the chest, cervical spine, and skull were negative. A focal mass lesion of the left sensory cortex was considered, and a pneumoencephalogram was performed which was entirely normal. The patient was discharged with the tentative diagnosis of multiple sclerosis and recommended that he return in six months for follow-up examination.

He was next admitted July 9, 1947. On this admission there was increasing difficulty with the function of his right arm and hand, and there was progressive gait disturbance, and three months prior to admission he had noted urinary urgency. Examination on this admission revealed moderate weakness of the right arm and leg, right hyperreflexia, a suggestively positive head and jaw reflex, positive Babinski on the right and a suggestive Babinski on the left. Intention tremor and past pointing was noted in the right arm, and there was impaired deep and superficial sensation in the right hand, including astereognosis. On spinal fluid examination the spinal fluid protein was now 36 mg. per cent and the colloidal gold curve was 0012100000. Jugular compression test was again negative. A myelogram was performed which was not entirely satisfactory; however, no significant defects were noted in the cervical region. The diagnosis of multiple sclerosis was again made, and after a course of hospital treatment he was discharged.

On the patient's third admission in December, 1947, there was increasing difficulty of his right upper extremity and increasing gait disturbance. The neurologic examination now disclosed marked pyramidal and posterior column damage with involvement of all four extremities, greater on the right. The patient's gait was ataxic and somewhat spastic. The coordination test disclosed adiadokokinesis and bilateral intention tremor. In view of the past work-up including a normal pneumoencephalogram and a negative spinogram, the diagnosis of multiple sclerosis of a progressive variety was again made and the patient was referred to the Corrective Rehabilitation Department for therapy.

When seen on his fourth admission January 11, 1949, the patient had marked difficulty in ambulation and because of the severe impairment in gait and the loss of sensation and control in his arms he was considered totally disabled. Neurologic examination revealed findings similar to those on his last admission; however, the findings were much more intense with severe involvement of the posterior and lateral columns. On this admission, the patient complained of pain in the right posterior cervical region with radiation into the right shoulder.

In reviewing this patient's case, it was noted that there were no findings at any time to suggest any significant cranial nerve involvement and that this patient's course was one of a progressive variety. The findings of incoordination and tremor noted in the extremities could be attributed to severe posterior column damage, and it was felt that a spinal cord tumor could account for all his findings. Therefore a repeat cervical myelogram was performed which revealed a constant block indicating an extramedullary lesion at C-4. A cervical laminectomy was performed, and an extra- and intradural dumbell neurofibroma was removed. Postoperative course was uneventful, and this patient showed marked neurologic improvement in the subsequent months and when seen two years later the patient was able to work a full schedule on his farm with the only complaint of ease of fatigue and mild paresis and numbness of his right arm and hand.

Summary.—This veteran had a three-and-a half-year history of progressive neurologic disability beginning in his right arm and then spreading to involve the other limbs. A diagnosis of multiple sclerosis was made on three separate admissions to the Minneapolis VA Hospital. Original laboratory procedures including pneumoencephalogram, spinal fluid examination and myelogram were not remarkable. The spinal fluid protein was never elevated beyond 60 mg. per cent and even though there was progressive neurologic impairment the spinal fluid protein actually decreased. The jugular compression test was never abnormal. A repeat myelogram performed on his fourth admission revealed a block at C-4, and at surgery a dumbell neurofibroma was removed.

These five cases, two with cervical cord tumors, two with brain tumors that involved the brain stem and cranial nerves, and one with myasthenia gravis, illustrate that even with the history of "so-called" remissions and exacerbations and suggestion of multiplicity of lesions, the diagnosis of multiple sclerosis requires constant scrutiny. Fortunately, four of these patients received a change of diagnosis during life to permit and receive specific therapy and in three of these (myasthenia gravis and two cord tumor cases) the results were most gratifying.

Treatment

As can be expected in all illnesses wherein the etiology is unknown a great number of drugs, agents, and techniques have been utilized in the treatment of multiple sclerosis. It is doubly difficult to evaluate the success of any therapeutic regime in this condition because of the inherent problems in establishing the diagnosis, the uncertainty of the particular course, and the natural tendency for the illness to remit. Even though there is no specific therapy and in spite of the fact that we have all seen cases of multiple sclerosis fail to respond or regress under treatment, a nihilistic approach is unwarranted. Individuals with this chronic neurologic disturbance look to the practitioner for hope, and help, and if informed that no treatment exists they may deteriorate emotionally as well as physically. Furthermore, many will seek out the unqualified, unethical practitioner. The challenge these patients and their families present should be met by an honest endeavor on the part of the respon-

he decision often favors

ROMYCIN*

HYDROCHLORIDE
TETRACYCLINE HCl *LEDERLE*

Compared with certain other antibiotics, ACHROMYCIN offers a broader spectrum of effectiveness, more rapid diffusion for quicker control of infection, and the distinct advantage of being well tolerated by the great majority of patients, young and old alike.

Within one year of the day it was offered to the medical profession, ACHROMYCIN had proved effective against a wide variety of infections caused by Gram-negative and Gram-positive bacteria, rickettsiae, and certain viruses and protozoa.

With each passing week, acceptance of ACHROMYCIN is still growing. ACHROMYCIN, in its many forms, has won recognition as a most effective therapeutic agent.

sible physican to "treat," fully realizing the limitations of any therapeutic program. A sincere medical interest on the part of the doctor, utilizing a positive dynamic approach, will result in many satisfying improvements. The increased awareness of corrective rehabilitation during the past decade along with newer non-specific pharmacologic agents make possible a broad therapeutic program.

For many young adults afflicted with multiple sclerosis, such a positive approach will bear dividends, if only to teach the patient how to adjust to his disability and utilize to full advantage the remaining motor function.

The full therapeutic regime includes the more commonly used drugs listed in the outline below: physical and corrective therapy, avoidance of physical and emotional stress, and employment of psychotherapeutic techniques.

Drug Therapy—Multiple Sclerosis

I. Vitamins and Tonics
    (1) Thiamine chloride (B_1) 100 mg. b.i.d. (O)
    (2) Vitamin B Complex—b.i.d. (O)
    (3) Vitamin E—Mixed tocopherols—wheat germ, 50 mg. t.i.d.
    (4) Vitamin B_{12} 100-1000u 3X week I.M.
    (5) Multiple vitamins
    (6) Crude liver extract (3-6 units weekly)
II. Vasodilators and Vascular Agents
    (1) Histamine—2.75 mg. (1 mg. of base) in 250 cc.—500 cc. N.S. intravenously X 20-30 days
    (2 Nicotinic Acid—50-100 mg. plus to produce flush reaction q.i.d.
    (3) Etamon—200-400 mg. I.M. b.i.d.
    (4) Amyl nitrate—inhalation
    (5) Papaverine—75 mg. q.i.d.
    (6) Dicoumerol—100 mg. plus daily to alter prothrombin time to 30-50 per cent of normal
III. Steroid Therapy
    (1) Cortisone—50-100 mg. daily X 30 days and/or
    (2) ACTH
IV. Anti-allergic Drugs
    (1) Histamine—as above
    (2) Pyribenzamine—50 mg. q.i.d.
    (3) Benadryl—50 mg q.i.d.
V. Spasticity Alleviating Drugs
    (1) Mephenesin—250-500 mg. plus q.i.d. (O)
    (2) Quinine—5-15 gr. t.i.d. (O)
    (3) Prostigmine—15-45 mg. of the hydrobromide q.i.d.
    (4) Atropine and atropine-like drugs
VI. Miscellaneous Agents
    (1) Piromen
    (2) Sodium succinate
    (3) Adenosine mono and triphosphate
    (4) Nucleotides
    (5) Isonicotinic acid hydrazide
    (6) Typhoid fever vaccine
    (7) Low fat diet

During an acute attack a combination of oral multiple vitamins, including large extra doses of thiamine, intravenous slow drip histamine infusion, Vitamin B_{12}, 1000 micrograms I.M., and physical therapy as required is an excellent beginning program to be followed for two to four weeks. If unsuccessful, the other pharmacological agents are to be given a trial.

The utilization of comprehensive corrective rehabilitation techniques concomitantly with the drug therapies will (1) aid in the prevention of secondary joint fixation, (2) prevent tissue breakdown, (3) keep the patient in positive protein balance, (4) teach the patient how best to handle himself in the presence of his various disabilities, (5) to utilize his residual capacities to fullest extent, and (6) synergistically the psychologic aspects of such a positive program will act as a catalytic factor, mobilizing an all out effort on the part of the patient. Even a bedridden multiple sclerotic patient, who can be rehabilitated to the use of a wheel chair with the potential of increased self-care activities, is a significant albeit minimal goal. Constant vigilance is required to prevent the development of immobilization and its attendant evils. Inactivity hastens the development of complications such as decubiti, contractures, protein and calcium imbalance, genitourinary infections and calculi formation, and draws heavily on the emotional health of the patient and also those that treat him.

Physical therapy can and does lessen these destructive complications. The patient undergoing dynamic corrective rehabilitation must be cautioned not to exercise to a state of physical exhaustion.

The physician with the above therapeutic armamentarium plus the benefits derived from physical therapy, and cognizant of the patient's and family's psychotherapeutic needs can and will be of utmost service to his multiple sclerotic patients.

Summary

The criteria for the establishment of the diagnosis of multiple sclerosis are reviewed. With the absence of the "time and place" formula the diagnosis should be made only on an exclusion basis, subject to change.

Five cases are reported that were originally diagnosed in error as multiple sclerosis.

The therapeutic program for each patient must be custom-tailored along a positive dynamic course, utilizing the various drugs available and exploiting corrective physical therapy to its fullest extent.

FUNCTIONING OVARIAN TUMORS

MALCOLM B. DOCKERTY, M.D.
Rochester, Minnesota

Following the discovery by Virchow of the production of bile in a pulmonary metastatic tumor originating from a hepatoma, it became apparent that utter lack of function was no longer implicit in the definition of a neoplasm. With acquisition of knowledge concerning tumors of ductless glands came the realization that such tumors produced, often in large amounts, the hormones that were native to their tissue of origin. Such anatomic and physiologic evidence of function as relates to certain ovarian neoplasms is the subject of this report.

Granulosa Cell Tumors.—Comprising perhaps 2 per cent of all ovarian neoplasms, this growth characteristically feminizes its host. Children so afflicted are sexually and somatically precocious, with an early onset of "menses." During the period of sexual maturity, patients who have such tumors exhibit amenorrhea or anovulatory bleeding, and infertility is almost invariably present. Older patients often experience a postmenopausal return of "menses," often accompanied by soreness and enlargement of the breasts.

With such a history, the causative tumor often may be recognized grossly as a granulosa cell neoplasm, for it is typically unilateral, solid, lobulated and encapsulated, with a tan cut surface that is reminiscent of liver sausage. The uterus is unduly enlarged, containing fibroids in 50 per cent of cases. When the patients are more than fifty years of age, cancerous changes are present in the uterus in 15 per cent of instances. The occurrence of unilateral or bilateral carcinoma of the breast is another interesting side effect, possibly produced by the estrogen elaborated by the ovarian tumor cells. Suppression "atrophy" of the contralateral ovary is observed among patients of all ages. The "plush" condition of the vaginal mucosa in postmenopausal women suffering from the effects of granulosa cell tumors is still another evidence of function of such tumors.

Microscopically, the tumor shows a basic composition of granulosa cells in a variety of patterns of interest to both the gynecologist and the pathologist. An admixture of theca cells frequently can be found on careful search. The cellularity of the tumor is such that failure of recognition usually results in an "overdiagnosis" of ovarian sarcoma.

Aggressive tendencies relating to recurrence and metastasis are observed in about 25 per cent of patients in the older age groups, wherein policies of radical surgical intervention are also dictated by the high associated incidence of uterine carcinoma. Irradiation is extremely useful when total removal has not been possible. Among younger persons with granulosa cell tumors, simple removal of the tumors has been satisfactory.

Theca Cell Tumors.—Occurring either in pure form or hybridized with granulosa cell tumor, this second member of the feminizing group is observed principally among older women.

Theca cell tumors are unilateral, solid, lobulated, encapsulated yellowish-brown growths of moderate size. Pathologic changes in the uterus, including endometrial carcinoma, frequently are observed and the uninvolved ovary is often atrophic.

Microscopically, masses of lipide-laden, plump, spindle-shaped theca cells alternate with zones of hyalinization in a picture that may be confusingly similar to that of a fatty fibroma. Escape from this diagnostic dilemma is often afforded by the finding of clusters of granulosa cells in the truly functioning growths. Although practically all theca cell tumors are benign, their treatment in older patients has been of necessity somewhat

radical because of the coexistent uterine pathologic changes.

Sertoli Cell Tumors.—Sertoli's cells are reputed to elaborate estrogen, and clinically feminizing tumors made up of these elements have been humans. Some investigators maintain that a human ovarian counterpart exists in the form of described in the testes of dogs and, rarely, also of certain rarely reported instances of tubular granulosa cell tumors.

Arrhenoblastomas.—Arising either from testicular remnants in the ovarian hilus or through an overgrowth of comparable elements in a teratoma, this masculinizing neoplasm induces amenorrhea associated with such conditions as infertility, hirsutism, changes in voice and atrophy of the breasts. Of the approximately 100 cases reported in the literature, the few in which necessary studies have been performed generally have exhibited decreased values for urinary estrogen and increased values for ketosteroids. Arrhenoblastomas, which are of a small average size, are characteristically solitary, solid, lobulated and encapsulated. Their local removal in young women has been followed by resumption of menses, pregnancy and parturition, and regression of hairiness and changes in the voice. Prolonged follow-up studies, however, reveal a 50 per cent incidence of recurrence and metastasis, indicating that such conservative treatment has not served the best interests of the patients.

Microscopically, many variations depart from the "average" picture of tubules resembling those of the testis, with intervening clusters of Leydig's cells. Sertoli's cells lining the tubules may secrete estrogen that neutralizes the male sex hormone of the interstitial (Leydig) cells. Such a valid (?) explanation has been offered to explain the absence of clinical masculinization sometimes noted in patients who have tumors that appear mature and differentiated. Interstitial cells are more abundant in the less differentiated growths, which usually produce the most pronounced degree of masculinization. Indeed, a few cases have been reported in which ovarian hilar proliferations of Leydiglike cells have produced masculinization even in the absence of any lesion deserving the designation of tumor.

Masculinovoblastomas.—Twenty case reports comprise the literature on this interesting growth, in which the pathologic features of an ectopic adrenal cortical carcinoma are linked with the clinical picture of Cushing's syndrome. The tumors presumably arise from adrenal cortical tissue sequestered within the ovarian hilus.

These growths are large, solid, friable carcinomas that fortunately are usually well encapsulated. Microscopically, they feature clusters of lipide-laden cells with sharp epitheliumlike outlines disposed in alveolar and trabecular patterns. Evidences of cellular anaplasia and pronounced pleomorphism usually have not been reflected in metastasizing aggressiveness, and many patients afflicted with these tumors have achieved permanent cure after simple oöphorectomy.

Dysgerminomas.—Comprising about 1 per cent of ovarian neoplasms, the dysgerminoma has been captioned a "neutralizing" tumor principally because of its frequent occurrence during prepubertal years and its occasional association with a state of pseudohermaphrodism. However, its removal does not alter the habitus of such patients. Since a number of these growths have been discovered during pregnancy, one wonders about the propriety of continuing to classify them as "neutralizing." Bilateral in a third of cases, dysgerminomas as a rule are large, soft, hemorrhagic and necrotic. Microscopically, the picture is exactly similar to that of seminoma testis, which likewise arises from primitive sex cells.

A discouraging 30 per cent five-year surgical survival rate indicates all too clearly that the body curves of the patients rather than the mortality curves in the past have fostered a somewhat conservative assault on this serious form of ovarian carcinoma.

Struma Ovarii.—As a producer of ovarian hormones, struma ovarii certainly stands on the side lines. However, this teratomatous tumor of thyroid tissue sometimes elaborates enough thyroxin to justify its inclusion in any group of functioning ovarian tumors. Basically, the functioning 5 per cent of such lesions are toxic adenomas rather than exophthalmic goiters and the patient's thyroid gland does not share the metabolic turmoil of its ovarian auxiliary. As a consequence, operations on the neck have not made these patients better risks for oöphorectomy. Peculiarly prone to undergo torsion of their pedicles, these tumors frequently induce ascites. Malignant changes eventually ensue in 5 per cent.

President's Letter

OUR 102nd MEETING

It may not be too generally known, but it is an accepted fact that the medical profession spends more of its time at postgraduate education than any other profession or guild. This is as it should be. The never-ending search for methods of cure and prevention is inherent in our philosophy of public service. Advances in scientific knowledge and improvement of techniques reveal themselves annually in improved mortality rates, decreased morbidity, and increased longevity. This dissemination of knowledge and the interchange of ideas takes several forms, best exemplified by hospital staff meetings, pathological conferences, county and state medical meetings, and specialty organizations, and the voluminous medical literature.

Our State Association assumes its rightful part in this postgraduate medical education program by attempting annually to present a program at its annual meeting which will be of interest and value to the profession of the state.

The value of our annual meeting is enhanced by the contributions made by our commercial exhibitors. They demonstrate improved technical instruments, inform us of improved therapeutic agents, make available for demonstration and inspection medical texts of all varieties. The value of their contribution cannot be overestimated.

This year your Committee on Scientific Assembly is introducing an innovation to our State Association meeting. Two and a half hours a day will be given to closed circuit television. This, of necessity, will decrease the number of formal papers that can be given at the meeting, and your officers and committee membrs are awaiting with a great deal of interest your reactions to such a program.

This year also we have a distinguished roster of guest speakers, and we welcome their contribution to our program. In addition, we have shifted the round tables to all three days of the meeting, and the topics will be discussed under competent moderators. I urge you all to make reservations for the round-table discussions as early as possible so that you will not be disappointed in attending the discussion of your choice. Programs and reservation cards will be sent to members around May 1.

Also, this year is the centennial of the Hennepin County Medical Society and we are very happy to join with the society in celebrating the occasion. Wouldn't it be interesting if by some magic means the founders of the Hennepin County Medical Society could attend our annual meeting? Their amazement can only be imagined, but we must remember that it is through the efforts of these original founders that our success as a county and a state organization was made possible. To them we owe our undying gratitude.

Your Committee on Local Arrangements, your Committee on Scientific Assembly, and all your state officers are eager to greet you and serve you at our annual meeting. We are also anxiously awaiting your reactions to the innovations in the program and hope for your constructive criticism.

Arnold O. Swenson

THE STATUS OF NEUROLOGIC RESEARCH

In the 19th and early 20th centuries, neurological research was principally devoted to the elucidation of anatomical pathways, the study of pathologic alterations aided by special staining techniques, and the careful clinical description and categorization of neurological disease. Advancements in research techniques and the revision of clinicians' orientation towards neurological disease have resulted in drastic changes in neurological research in recent years.

The development of electroencephalographic and electrocortiographic techniques as well as the application of the cathode ray oscilloscope and of strichnine neuronography in human and animal experiments has provided physiological information unobtainable by older techniques. The adaptation of the nitrous oxide technique by Schmidt, Kety, and other investigators has clarified many speculations concerning cerebral circulation. The physiological functioning of the nervous system has now been demonstrated to be intimately concerned with a variety of enzymatic and other chemical reactions. The clinical applications of neurochemistry was strikingly demonstrated by studies such as those indicating Vitamin B_1 (thiamine-diphosphate) to be essential to the aerobic metabolism of nervous and other tissues. Failure in aerobic metabolism brought about by Vitamin B_1 deficiency results in the clinical symptomatology of polyneuritis as well as in central nervous system manifestations. Other recently developed techniques include tissue culture and phase microscopy which have contributed toward the improved diagnosis of poliomyelitis and other virus infections and have accelerated the development of anti-viral vaccines.

Clinical research methods have also undergone marked changes in the past few years. A dynamic approach to nervous system disease has replaced the purely descriptive and categorizing type of neurology. The advances in anatomical, physiological and chemical knowledge are being employed to improve the diagnosis and therapy of neurological disease. Newer techniques such as arteriography and other neuroradiological procedures have produced marked improvement in the neurological diagnosis. Among the most dramatic contributions of clinical neurologic research is the development of rehabilitation in the neurologically disabled patient.

The emphasis on newer methods in basic neurologic research and the accentuation of dynamic clinical neurology has contributed significantly to a greater understanding of neural mechanisms and a sounder approach to neurologic diagnosis and therapy.

MAYNARD M. COHEN, M.D.

MINNESOTA POLL

The *Minneapolis Sunday Tribune's* Minnesota Poll, published January 23, 1955, concerned itself with attitudes toward physicians and showed that in Minnesota: two-thirds of the people considered doctors' fees reasonable; more than four out of five people are satisfied that doctors "take a personal interest in their patients and their troubles"; 87 per cent believe doctors are better trained nowadays than they've ever been, and 68 per cent believe people in this country would be worse off if we had federal control of doctors.

This is a public relations testimonial of which physicians are proud. But, recall the repeated sage comment of the late Dr. J. C. Litzenberg, "*Any* physician can make the right diagnosis and undertake the correct treatment in 80 per cent of the patients who come to him. But what we want to train here at the University of Minnesota are physicians who can also be right in that other 20 per cent." Then recall also the anonymous research worker who contended that unless the proof of a hypothesis was so forthright that it fairly hit you in the face, it wasn't convincing enough to let you accept the hypothesis as correct. From this Minnesota Poll we have, in a general sort of way, that dissenting 20 per cent; e.g., the poll reports that 32 per cent of the people aged sixty and older, 25 per cent of the labor union members, 24 per cent of the men, 22 per cent of the Democratic-Farmer-Labor voters, and 20 per cent of the independent voters think that the country would be better off if medical care were controlled by the federal government and doctors were under federal regulation.

Apparently, Minnesota physicians, however proud they have a right to be about having pleased from two-thirds to seven-eighths of their patients, must offer still more to please the unconvinced 20 per cent. We could just assume that they are the incorrigibles, no matter how you look at them, but somehow, we're sure, the Litzenbergian principle will prevail and we'll continue to try to render satisfying service to 100 per cent of our patients.

H.G.M.

HOW A LOCAL BANKER MAY SERVE THE PHYSICIAN

We believe that a local bank serves the physician by making available to him a safe storage place for money; by providing personal and business checking accounts; by advancing long-term financing for his building and equipment; and by granting short-term financing for temporary needs. These are the major items of service which are in turn supplemented by other less routine services furnished by the banker who is his financial consultant.

The first item mentioned is, of course, one of the basic functions of banking, and within its structure, a convenient safe method of storing funds is provided. These funds are available immediately for the use of the physician, and in the meantime can be used by the bank in the form of loans, to develop and strengthen the trade territory in which both the physician and the bank operate.

Many physicians are noted for their lack of interest in the maintenance of good records. The bank provides a checking account service which is invaluable in this respect to provide legal receipts for bills paid, and to provide good evidence for income tax records. This service is important both from the standpoint of the professional or office account, as well as for the personal account, and in many cases is the only record maintained in the latter area.

In many communities, the physician is expected to maintain complete and extensive office facilities to supplement the hospitals in his town. These facilities may take the form of a modern clinic for several doctors, or doctors and dentists combined, and represents a considerable investment of money. Long-term financing is required to enable these facilities to be constructed and paid for on an orderly basis, and the banker helps to provide these funds as well as aids in making decisions regarding the size of the project and the proper location for it. Even where the office is maintained in rented quarters, the physician's investment in equipment and supplies can be quite large and will require relatively long-term financing. Short-term financing for other temporary needs is readily available at commercial banks for the purpose of financing accounts receivable and unusual temporary expense items and supplies.

After the physician is well established in his community and has acquired and paid for his "plant and equipment," the banker is often called upon to serve in less routine ways. The physician can properly look to him for assistance in investing his funds. The banker can discuss the field of investment generally, and suggest to the doctor the type of investment he feels might be best suited to his needs, pointing out the safety features, the rate of return, and call attention to the speculative nature, if any, of the investment under consideration. Ordinarily, too, the banker is an excellent source of information regarding community projects of various kinds that professional people are called upon to support, and by merely placing a telephone call to the banker, reliable information of this kind can be obtained.

In addition, we feel that the banker and the doctor share common interests in two very important community matters. Both are interested in the over-all welfare of the people in their trade area, and the bank, by careful and judicious use of credit, builds its community in terms of improvement, of employment potential, by attracting new businesses and aiding established firms in their growth, and therefore develops a larger clientele for the work of the doctor. In recent years, more and more families are coming to the bank for family credit and the banker helps these people stabilize their personal affairs, which in turn eases the collection problem for the doctor. It is also our feeling that both the medical profession and the banking profession are among the strongest proponents of the capitalistic system, both believing that socialization of their professions would in the long run not operate to the advantage of most of the people. Both of these professions have a responsibility to make these views known within their community, and it would therefore seem that the banker and doctor can function as a team, not only strengthening each other in their ability to serve, but in turn strengthening the community they both serve, and from which they draw their livelihood.

Walter V. Dorle
President, Northwestern State Bank
Saint Paul, Minnesota

HISTOPLASMOSIS IN MINNESOTA

Waring, in Minnesota Medicine, August, 1954, presented a fine article on non-tuberculous cavities of the lung, which summarizes the picture of the fungus infections, coccidioidomycosis, histoplasmosis, and actinomycosis; these three represent the vast majority of fungus infections of the lung. Waring illustrates the similarities and dissimilarities between these diseases and tuberculosis, and emphasizes many practical points in differential diagnosis. This becomes increasingly important to physicians in Minnesota because of new evidence of the existence of histoplasmosis in the state on a scale hitherto unsuspected.

The fungus, Histoplasma capsulatum, is widely distributed in nature, mainly but not exclusively in the Mississippi Valley. Following human infection, the skin test with histoplasmin converts from negative to positive within one to two weeks after the onset of illness, and remains positive for years. This skin test may be used to measure the extent of human infection with the fungus in any area. There is no evidence of person-to-person communication of infection. Age, as well as residence, will affect expected histoplasmin sensitivity, since children may have a much lower frequency of reactions than the adult population.

Using such survey techniques, Furcolow et al have shown, in the Cincinnati, Ohio, area, that 15 per cent of children five years old reacted positively to histoplasmin, the rate rising steadily to reach a high of 80 per cent positive at age eighteen years. This rate curve is similar to that of children in Kansas City, but a little lower. The same children reacted positively to tuberculin in less than 1 per cent at age five, rising to about 5 per cent at eighteen.

In May, 1954, tuberculin and histoplasmin tests were given to 5,487 school children in the grade and high schools in Wright County, in central Minnesota, and to 199 adults connected with these schools. Of the children, sixty-five (1.2 per cent) reacted positively to tuberculin and 404 (7.3 per cent) reacted positively to histoplasmin. Of the adults, forty-five (22.6 per cent) were positive to tuberculin, and thirty-two (15 per cent) were positive to histoplasmin. Further analysis of the survey will be available soon.

Histoplasmosis has been recognized as occurring in Minnesota in epidemic form on at least two occasions: in 1948 in the Detroit Lakes area, and in 1949 and 1953 in Wright County. Waring points out that the lungs are involved in about 50 per cent of cases reported in the literature, and that about 20 per cent of reported cases are in infants.

It seems apparent that histoplasmosis infection may not be as infrequent in Minnesota as hitherto believed, and that the disease occasionally occurs in localized epidemics. Because of frequent pulmonary involvement, the disease must be considered in the diagnosis of respiratory illness, and it may be the cause of unexplained illness in children.

D. S. Fleming, M.D.

ACCIDENTS, A KILLER OF OLD AND YOUNG

Readers of Minnesota Medicine have had several topics of accidents brought to their attention during the past several months in a series of articles focused on accidents as the prime killer of children. In this issue still another is presented: *"Choking Accidents."*

Are you teaching young parents the dangers to which their children are exposed? Are you using the new safety vaccine?

T.C.C.

Evidence on all sides shows that the enduring health programs are those the people have understood and those they have had a hand in developing.—Hugh R. Leavell, M.D., Dr. P. H., *American Journal of Public Health,* November, 1954.

The Dean's Page

THE PROCUREMENT OF ANIMALS FOR RESEARCH

The 1949 Legislature passed an act "to promote scientific research and instruction in animal and public health by making available to educational and scientific institutions, unclaimed and unredeemed animals impounded by public authority in animal pounds" and "to provide licenses therefor and penalties for violations thereof." The title of this act clearly indicates the intent of the 1949 Legislature to aid educational and scientific institutions in the procurement of animals for teaching and research purposes for the benefit of both human beings and animals.

Primarily, through the Antivivisection Society and similar groups, resistance to the provisions of this law was encountered. It became obvious that several points in the law needed strengthening. First, the definition of "animal pound" was not sufficiently explicit to prevent legal arguments. This controversy centered around the question of whether or not a privately owned kennel impounding stray animals through a contract with a municipality was subject to this law. The second difficulty with the original act was the lack of a specific procedure to be followed in the event of an alleged violation of the law.

The 1955 Legislature is to be commended for correcting the weak points in the original act of 1949. Amendments were passed which clearly stipulate:

> "Any public or private agency, person, society or corporation having custody of animals which are seized under authority of the State or any political subdivision of the State must make available to licensed institutions all animals unclaimed and unredeemed by their owners . . ."

One of the most effective amendments was as follows:

> "Any establishment which fails to comply with these provisions shall become immediately ineligible for any further public funds from any county or municipality."

Rapid enforcement procedures and an arbitration agency were added in the following amendment:

> "Upon receipt of a sworn statement by an authorized officer or employe of any institution licensed hereunder of non-compliance by an establishment with these provisions it shall be unlawful for the treasurer of any municipality or other political subdivision of the State to pay any public funds to such establishment until the complainant withdraws its statement of non-compliance or until the State Livestock Sanitary Board shall either determine that the complaint of non-compliance was without foundation or that the establishment has given adequate assurance of future compliance, and the treasurer of such municipality or other political subdivision has been notified of such determination in writing. If it appears upon the complaint of any person that any officer, agent, or employe of such establishment is violating or failing to carry out the provisions of this section, the Attorney General or County Attorney of the county in which the establishment is located, in addition to any other remedies, may bring an action in the name of the State of Minnesota against any such establishment, officer, agent, or employe thereof to enjoin compliance with this section."

Chapter 195 of the session of the laws of the 1949 Legislature, as amended by the 1955 Legislature, stands as a milestone in the course of progress in experimental medicine. It clearly indicates strong public support for scientific progress. The members of the Legislature who made this law possible are to be congratulated for a job well done!

HOOVER COMMISSION REPORTS ON MEDICAL SERVICES

The medical services report of the Hoover Commission (on Organization of the Executive Branch of the Government) was sent to Congress recently.

The more important recommendations are: (1) Establish a Federal Health Council; (2) Provide contributory health insurance for military dependents and for personnel of the Coast Guard, the Public Health Service and the Coast and Geodetic Survey, and for dependents of the latter three groups; (3) Regionalize military medical services, with one service responsible for each region; (4) Tighten up ability-to-pay requirements in VA, and codify VA laws and regulations; (5) Virtually wipe out the present Public Health Service hospital and medical care program.

The Medical Task Force of the Hoover Commission made studies which report that United States spending for medical programs and compensation totals $4.1 billion a year and that the federal government is responsible in whole or in part for the medical care of 30 million people. These facts are reported in a recent issue of the American Medical Association Washington Letter.

The Letter states:

> "It is expected that legislation shortly will be introduced to carry out the recommendations. In a legislative sense, the Commission and Task Force suggestions carry only what weight the Congress wants to give them. The major medical recommendation of the first Hoover Commission (1949) was for a united medical administration to take over most of the medical responsibilities of the federal government. Hearings were held in Congress on this recommendation, but it was not put into effect."

AMA COMMENTS ON HOOVER REPORT

Recommendations of the Hoover Commission on non-service-connection disability regulations were surprising to the American Medical Association, according to a recent Secretary's Letter. The Letter states:

> "It was surprising to many of us . . ., and certainly to the nation's taxpayers, that the Hoover Commission, in announcing its report on federal medical services on Monday, February 28, junked the major recommendation of its own 16-member Medical Task Force. At the last minute of deliberations, it substituted instead proposals which will expand instead of curtail government medical care for veterans with non-service-connected disabilities."

The Letter goes on to say that in its study report to the commission, the Medical Task Force recommended that veterans with non-service-connected disabilities receive hospital care if the need for such disability is established within three years following discharge from active duty. Members estimated that the number of potential patients with non-service-connected disabilities would be reduced from 17.5 million to about 3 million, with an estimated annual savings of $150,000,000.

"The commission, however," states the Letter, "chose to reject the cut off provision and recommended that this service be reduced through a closer financial screening of applicants. This recommendation, as we all know, already has been tried and proved to be ineffective."

Inconsistent Views

It is noted that the commission has made recommendations which were not in keeping with recommendations of its Medical Task Force. The AMA comments:

> "While the Medical Task Force did recommend non-service-connected out-patient care, it was to be within the framework of the three-year cut off date. The commission, in eliminating the three-year eligibility clause, chose to retain the provision of out-patient service, which in the past has been available only to veterans with service-connected disabilities. This out-patient provision would actually skyrocket the cost of veterans' medical care."

In conclusion, the AMA states that the Commission has reverted from its original objective:

> "To remove the three-year time limit and, at the same time, furnish the non-service-disabled veteran out-

patient care in veterans' hospitals is certainly not in keeping with the commission's objective of trying to eliminate wasteful government spending and the unnecessary intrusion of the federal government in private affairs."

SURPLUS PROPERTY SOUGHT FOR HEALTH FACILITIES

According to a House Government Operations Subcommittee, a new Defense Department regulation may be preventing distribution of surplus property to health and educational institutions. The subcommittee, under direction of John W. McCormack (D., Mass.) is investigating the charges. The regulation requires that certain salable surplus items in the military services be placed in a "capital account," to be sold at prices said to average less than 5 per cent of their acquisition cost. A recent AMA Washington Letter reports that a system for free distribution to health and educational institutions has been in existence for some years, under supervision of the Department of Health, Education and Welfare.

The subcommittee had before it a bill which would amend the present law to:

> "1. Require all departments to release surpluses if the states and other non-profit agencies want them, and if HEW approves.
>
> "2. Remove after one year any restrictions on resale or disposal of surplus property previously acquired, and permit immediate passage of title in future acquisitions.
>
> "3. Allow for unrestricted transfer of surplus property ownership among federal and state agencies."

RURAL HEALTH LEADERS GATHER

Community efforts to bring better health to rural areas was the point of emphasis at the recent 10th National Rural Health Conference in Milwaukee. About 500 physicians, farm organization officials, agricultural extension workers, farmers and others met to discuss mutual rural health problems and projects.

Subjects of discussion included farm and home safety, family responsibility for health, using available health and medical care resources, and how the job is done. Dr. F. S. Crockett, Lafayette, Indiana, chairman of the AMA's Council on Rural Health, said:

> "Our first ten years in this important endeavor of creating more healthful living for people in rural areas has produced a remarkable unity of purpose between the medical profession and farm people. Medicine is no longer a job for the doctor alone—it is a community problem, too."

One of the striking aspects of the conference was its deep personal basis—the feeling that the participants were not talking about "problems" or "goals" or "programs" but about people, the rural people whose work is the mainstay of the entire nation's well-being. According to an AMA news release on the meeting, "The accent was first of all on individuals, then families, then communities. The individual man's responsibilities and tasks were foremost, while the family unit was stressed as the starting-point for cooperative effort on other levels."

Looking Both Ways

Theme of the meeting was "Looking Both Ways"—to past achievements and future goals. Dr. Leonard W. Larson, Bismarck, N. D., AMA Trustee, summing up the meeting, noted that doctors have been in the minority at the ten national conferences and that "their viewpoint, although freely expressed, has not dominated the discussions."

"This is as it should be," he continued, "for the people know best what is available and what is needed to improve the health condition of the farmer. The doctor can tell them how to utilize existing facilities and how, from the medical viewpoint, he can be of assistance in the attainment of their objective."

"JUST KEEPING UP" TAKES TIME

The average American physician, who puts in a sixty-hour work week, spends about ten hours a week just keeping up his education, a recent American Medical Association survey shows.

And, even with this exacting schedule of hours, most physicians surveyed said they wished it were possible to spend much more time keeping up to date with medical progress.

Dr. Douglas D. Vollan, assistant secretary of the Council on Medical Education and Hospitals, reported on the survey of the physician's career-long education in a recent issue of the AMA Journal. He stated:

> "Every year, every month, and every day brings new changes in the panorama of knowledge of human biology,

human disease, and related scientific fields. With this knowledge comes new skill in the prevention, diagnosis, and treatment of the ills that plague mankind. . . . What may have been acceptable treatment for one condition 20 years ago might now be considered less than worthless."

Therefore, it is "absolutely essential" for the physician to continue his education as long as he practices medicine. The Council survey found out from about 5,000 physicians and numerous postgradate education facilities just how it's done.

According to the survey, the surveyed physicians said they spend a yearly average of 667 hours (about 83 eight-hour days) in the five general fields of learning after college—reading, professional contacts with other physicians, attending hospital staff meetings, going to medical society meetings, and taking formal postgraduate courses.

Reading Important

Most physicians said reading is the most important way to learn, and wished they had more time for it. A third of these 667 hours are spent in reading. Another third of the time is in professional contacts with other physicians, since "bedside consultation" is probably one of the best ways to learn. Physicians spend from one day to as much as three months a year taking courses, which they ranked second in educational importance. Those surveyed said they would like to spend 200 per cent more time in postgraduate courses.

Dr. Vollan, in summing up the report, quoted a comparison of the American physician "to a shiny new automobile, the product of a very large initial investment but one that requires constant care, repair, and refueling in order to do the job for which it is intended."

HOBBY SAYS AMA WILL ACCEPT REINSURANCE

Secretary to the Department of Health, Education and Welfare, Mrs. Oveta Culp Hobby, believes the American Medical Association will show a turnabout and accept the government's reinsurance plan. Testifying in support of the President's national health program recently, Mrs. Hobby deprecated suspicions that reinsurance is a leadup to socialized medicine.

In response to questioning, Mrs. Hobby definitely indicated that she expects the AMA will not oppose reinsurance. One of the strongest deterrents to passage last year was AMA's claim that it was an opening wedge to socialized medicine. "I think when you come to question AMA," Mrs. Hobby stated, "they will not say it is an opening wedge." Mrs. Hobby continued:

> "I thought that old socialized medicine ghost was dead. Reinsurance is just an attempt to help men and their families help themselves. I don't believe people want socialized medicine, but they do want a way to pay medical bills. We must find a way by which they can pay those bills. If we don't do it by a voluntary way, then it must be done by subsidy or by compulsory health insurance."

This proposal is still being studied by the AMA and no commitment has yet been made on approval or opposition.

PRACTICAL COURSE FOR DOCTORS-TO-BE

What advantages do general practitioners have over specialists? How does a young doctor start his practice? What are some of the early problems he faces, and how can he solve them to his own and the community's advantage?

These are some of the questions which are discussed in a course on "The Practice of Medicine," offered at the University of Colorado School of Medicine. This course, which is intended to give medical students practical advice on the situations they will face at the start of their careers, is described by Dr. Gertrud Weiss, associate professor and acting head of the department of preventive medicine at the school, in the March issue of *The Journal of Medical Education.*

The study, which is offered in the junior year, is based on case history presentations, which are selected in advance. The students have time to study the cases, which cover such problems as the choice of locality and office space, relations with other doctors, fee setting, religion and patient attitude, and the business end of medical practice.

An appropriate resource person from the community is invited to appear at the scheduled seminars to discuss the particular case with small groups of students. Participation by the students is encouraged, and the lecturer often asks the students how they would solve the problem under discussion *before* he presents his lecture.

At present, a question which perturbs many medical students is the decision to enter general practice or to specialize. This problem is handled by a panel discussion between a general practitioner, an obstetrician, a pediatrician and an internist. Also, two general practitioners from small communities describe their practice and the situations they face. Dr. Weiss points out that this was the first time the students had met and been taught by general practitioners, and yet a poll taken at the end of the year showed that almost half of the junior class intended to enter general practice.

Public Health

STATE DENTAL HEALTH PROGRAM HAS MANY PHASES

Dental health has been a major concern of the Minnesota Department of Health for the past twenty years. It is recognized today as a legitimate public health concern because of the universal scope of the problem and the increasing effectiveness of preventive measures. In line with the philosophy that practicing dentists should have a basic knowledge of dental public health problems and programs, a series of lectures in this field was started in the School of Public Health, University of Minnesota, during the winter quarter of 1955, and will continue during winter and spring quarters each year.

The health department's dental health staff is much too limited to meet the numerous requests for help that come from all parts of the state. Hence, the plan usually followed is to give aid in setting up local programs with the co-operation of the dentists, public health nurses, school authorities, and citizen groups in communities requesting help, and then to turn over operation of the program as far as possible to the local people.

Outstanding dental health programs now in operation under the sponsorship of the Minnesota Department of Health include the following:

Topical Fluoride.—Three entire counties, comprising a total of 12 communities, plus nine other individual communities, have been aided in carrying out programs involving the topical application of fluoride to the teeth of children in grades 2, 5 and 8. Two new programs in this area are already planned for the fall of 1955. These topical fluoride programs provide field experience for senior dental hygiene students from the School of Public Health, University of Minnesota. The students assist professional staff members of the Section of Dental Health and the local dentists who give the fluoride treatments. Topical application of fluoride to children's teeth has been shown to reduce dental caries incidence on an average of 40 per cent.

Fluoridation of Community Water Supplies.—Projects in this area have been aided and promoted in 50 Minnesota communities. This program has been approved by the American Medical Association, American Public Health Association, and many other responsible professional groups. It has been demonstrated that continuous use of properly fluoridated drinking water by children during the period of tooth development reduces dental caries on an average of 65 per cent.

Research.—The Section of Dental Health is currently working on two research projects. The Askov demonstration was planned to demonstrate how much improvement can be effected in children's dental health when all known and available protective methods are used. This demonstration is now in its seventh year. Annual reports are published and are available on request. The other research project is being conducted in Mound, to determine the comparative value of sodium silicofluoride and two-per-cent sodium fluoride in controlling dental caries. A third study—on the effects of brushing the teeth with stannous fluoride —is planned to start in Bloomington schools next fall.

School Programs.—The Section of Dental Health sponsors and assists in a statewide dental health education program in all schools that wish to participate. During 1954, this program included 404,925 pupils in 3,101 public and parochial schools. (In the large cities, school boards operate their own school dental health programs.) Eighty-one of Minnesota's 87 counties were represented in the statewide program sponsored by the Department of Health.

Community Programs.—Each year the Section of Dental Health works closely with the Minnesota State Dental Association in planning and promoting educational programs for National Children's Dental Health day. These programs include radio and television broadcasts, exhibits, film showings, talks by dentists, and the distribution of Dental health literature.

In addition to these activities, staff members of the Section of Dental Health give many talks to P.T.A. groups, civic organizations, and schools, and participate in a number of conferences, workshops. short courses, and university classes. Last December, the Section of Dental Health participated in the first joint conference held in Minnesota for school superintendents, physicians. and dentists. Dental health conferences have been held for youth leaders in six Minnesota counties, in collaboration with the State Dental Association. Recently a county-wide educational program was carried out in Pope county, when every school in the county was visited by a team of dental health educators. Section of Dental Health personnel assisted at a cavity detection x-ray exhibit at the Minnesota State Fair last year.

SOCIAL EVENTS

SUNDAY, MAY 22

6:30 P.M.—SPORTS EVENTS DINNER, Minneapolis Golf Club. All participants in golf, archery and skeet and trap shooting are invited to attend with their wives, a joint sports events dinner after the Sunday afternoon sports events.

MONDAY, MAY 23

Luncheons

12:15 P.M.—American Medical Women's Association, Inc., Minnesota Chapter. All women physicians are invited to attend.
12:30 P.M.—Minnesota Medical Foundation, Junior Ballroom, Hotel Radisson.
12:30 P.M.—Minnesota Society of Clinical Pathologists. Curtis Hotel.
12:30 P.M.—Minnesota Chapter, American College of Chest Physicians (place to be announced).

Dinners

6:00 P.M.—Minnesota Academy of General Practice. Ballroom, Hotel Radisson.
6:00 P.M.—Reunion, Class of 1905. Hotel Radisson.
6:30 P.M.—Minnesota Society of Clinical Pathologists. Curtis Hotel.

Open House

9:00 P.M.—Minnesota State Medical Association. Ballroom, Hotel Radisson.

TUESDAY, MAY 24

Dinner

7:00 P.M.—Minnesota State Medical Association, Annual Banquet, Ballroom, Hotel Radisson.

ROUND TABLES

Hotel Radisson—12:15 P.M.

MONDAY, MAY 23

Newer Insulins ....Moses Barron, Minneapolis
Office Treatment of Foot Complaints
W. J. McDonald, Crookston
Diverticulitis of the Colon..David P. Anderson, Austin
The Injured Nose ....Jerome A. Hilger, St. Paul
Oxygen Therapy in the Premature Infant
R. P. Buckley, Duluth
Robert W. Hollenhorst, Rochester
Disorders Simulating Coronary Disease
Asher A. White, Minneapolis
The Changing Status of Cesarean Section
C. O. McCormick, Indianapolis, Ind.

TUESDAY, MAY 24

Office Gynecology ......Edward A. Banner, Rochester
Emergency Treatment of Head Injuries
Wallace P. Ritchie, St. Paul
Blood Transfusions in Therapy
T. H. Seldon, Rochester
Eczema in Childhood
Albert V. Stoesser, Minneapolis
Vaginal Procidentia and Stress and Continence
J. H. Pratt, Rochester
The University In-Patient Psychiatric Service for Children..Reynold A. Jensen, University of Minnesota
Defibrination Syndrome
Harold A. Oh, Royal Oak, Michigan

WEDNESDAY, MAY 25

Spinal Puncture Headache......L. R. Gowan, Duluth
Anti-hypertensive Drugs
Arthur C. Kerkhof, Minneapolis
Problems of Sudden Death
Arthur C. Aufderheide, Duluth
Treatment of Birthmarks ....John F. Schmid, Duluth
Urethral Strictures in Young Females
Edward J. Richardson, St. Paul
Edward L. Strem, St. Paul
Convulsive States ......Joseph A. Resch, Minneapolis
Pregnancy Associated with Heart Disease
John E. Faber, Rochester
Fulminating Eclampsia
Jack A. Pritchard, Cleveland, Ohio

GENERAL SESSION

Minneapolis Auditorium

MONDAY, MAY 23

Morning Session

A.M.

8:30 Visit Scientific and Technical Exhibits Auditorium

9:00 Closed Circuit Color Television ....Auditorium
Surgical Procedures—General Surgery

Intermission

10:15 Visit Scientific and Technical Exhibits Auditorium

11:00 RUSSELL D. CARMAN MEMORIAL LECTURE
"The Position of Radiology in Cardiovascular Diagnosis"
Fred J. Hodges, Ann Arbor, Professor and Chairman Department of Radiology, University of Michigan

11:30 MINNESOTA HEART ASSOCIATION LECTURE
"Diagnostic Cardiac Silhouettes and Electrocardiograms"
Arthur Master, New York, Associate Clinical Professor of Medicine, Columbia University

P.M.

"Anticoagulant Therapy"
John J. Boehrer, Minneapolis

"Thorazine and Rauwolfia"
C. O. Erickson, Minneapolis

4:30 Adjournment

ARCHERY TOURNAMENT AT ANNUAL MEETING

The First Archery Tournament for physicians will be held at 1:00 p.m., Sunday, May 22, just prior to the annual meeting of the Minnesota State Medical Association. Nokomis Archery Range, located in the park adjoining Lake Nokomis on the corner of 50th street and 54th avenue south, Minneapolis, will be the scene of this contest.

This is the first time that an archery contest has been offered as one of the sports events sponsored by the Minnesota State Medical Association. As far as is known, this is the first archery tournament ever offered in the United States exclusively for members of the medical profession. This is an experiment, and it is hoped that a sufficient number of physicians will participate in this contest to justify repeating it in future years.

The contest will be simple and not too demanding. A Junior American Round will be shot consisting of 30 arrows at 50 yards, 30 arrows at 40 yards and 30 arrows at 30 yards. Two classes of archers may compete—an instinctive group which shoots without the aid of a bow sight and a free style group which uses a bow sight. Suitable trophies will be presented to the first three winners in each class. Entrance fee will be $1.00.

Robert Rhode, Minnesota State Archery champion and United States National Target champion, will set up and conduct this archery contest. In June, Robert Rhode will be the American representative to the International World Championship Archery contest to be held in Helsinki, Finland.

Participants in sports events are invited to attend with their wives a sports events dinner at 6:30 p.m., Sunday, May 22, at the Minneapolis Golf Club, South Cedar Lake Road and Flagg Avenue, following the various events of the day. Tickets are $4.50, gratuity included. Entertainment for doctors' wives will be provided during the afternoon. This is an informal dinner, and sports participants are urged to attend the dinner as they are.

The success of this contest requires the participation of all physicians who are archery enthusiasts. Contact either Carl O. Rice, M.D., 1635 Medical Arts Building, Minneapolis 2, or George M. Tangen, M.D., 1427 Medical Arts Building, Minneapolis 2, for further details on this event.

CHOLANGIOGRAPHY

(Continued from Page 234)

Conclusions

A method of cholangiography has been described which seems to fulfill the requirements for a rapid, simply performed procedure. It is placed at the stage of the operation which allows progress with minimal delay. In seventy-five cases studied, the x-ray pictures resulted in as good exposures as by any other technique heretofore employed for the introduction of dye into the common duct. It can be employed in acute cases in which any of the techniques previously described probably could not be used.

Minnesota Academy of Medicine

Meeting of April 14, 1954

The regular monthly meeting of the Minnesota Academy of Medicine was held at the Town and Country Club on Wednesday evening, April 14, 1954. Dinner was served at 7 o'clock and the meeting was called to order by the President, Dr. E. A. Regnier, at 8:30 p.m.

There were fifty-one members and two guests present.

Minutes of the March meeting were not read because of the length of this evening's program.

Upon ballot, the following men were elected as candidates for membership in the Academy:

Harold E. Miller	Minneapolis
J. P. Medelman	Saint Paul
Bernard G. Lannin	Saint Paul

The following were elected as officers for the coming year:

Charles N. Hensel	President
Frederick H. K. Schaaf	Vice President
Robert E. Priest	Secretary-Treasurer (re-elected)

Dr. Priest read the Secretary's annual report and also the Treasurer's annual report; both were accepted.

The scientific program followed:

Dr. Ben Sommers, Saint Paul, read his inaugural thesis entitled "Problems of the Clinical Diagnosis and Classification of Ventricular Hypertrophy." Lantern slides were shown, and cases were reported.

Discussion

Dr. Joseph Borg, Saint Paul: I think we are very fortunate in having this subject brought to us, as it should be occasionally. It is very humbling to have cases brought to our attention, as errors in diagnosis are so frequent. We can learn much from an exchange of experiences in these patients, and I should like to mention at this time two interesting cases.

One was a girl, aged sixteen, who had hypertrophy of the left ventricle and who was seen first in the early stage of myocardial failure. In spite of the fact that this was her first decompensation, she failed to respond to all measures available and gradually pursued a downhill course to death in about three months. At autopsy a marked hypoplasia with narrowing of the entire aorta, associated with cardiac hypertrophy and chronic passive congestion, was the only finding.

The other patient was a boy, aged fifteen, who had relatively minor complaints, especially nausea, vomiting, and abdominal distress, with a markedly enlarged heart and left bundle branch block. He died this morning [April 14, 1954]. He had a loud, rough systolic murmur, transmitted over the entire chest, heard best at the left sternal border and thought to be probably due to an interventricular septal defect. Cardiac catheterization, however, showed no abnormality. At autopsy, the heart showed general enlargement, weight 1000 grams. No valve defect or congenital abnormality was found. The myocardium showed large areas of fibrosis, the significance of which is as yet undetermined.

These cases illustrate difficulty presented in diagnosis. Many cases of ventricular hypertrophy are probably due to previously existing hypertension, but obviously there is no reason for arriving at such a conclusion simply because no other reason for enlargement is found.

Dr. T. A. Peppard, Minneapolis: I have been delighted to hear Dr. Sommers' splendid presentation. We all see occasional cases with cardiac enlargement, which go on to failure and death, in which the autopsy does not explain the cardiac hypertrophy; these are then termed idiopathic. I am interested in the familial type, of which Dr. Sommers speaks, because I was early conditioned to consideration of the constitution in relation to internal diseases. I should like to ask Dr. Sommers whether he believes that relative coronary insufficiency might act as a possible cause of the hypertrophy.

Dr. Moses Barron, Minneapolis: I want to compliment Dr. Sommers for his very interesting presentation of a series of cases on idiopathic cardiac enlargement. The mechanism of cardiac enlargement in hypertension is not entirely clear, unless there be some relation between the extra strain in hypertension to the muscular strength. We think we can tell whether the heart muscle is normal by examining it microscopically. However, it is conceivable that the heart muscle may appear normal histologically while at the same time it is weak physiologically; an inherently weak heart muscle may enlarge under normal blood pressure just as a normal heart muscle may enlarge with increased blood pressure. The fibrosis and pathological changes which we wrongly call myocarditis may result when the weak muscles have to work even against normal pressure.

Dr. Sommers, in closing: I am very grateful to the doctors for their discussion. In regard to Doctor Peppard's question concerning the possibility of coronary insufficiency to account for left ventricular hypertrophy, I can only say that the heart muscle in the two cases I presented was searched diligently for subendocardial fibrosis, which should be present if coronary insufficiency had developed. No fibrosis was present.

Dr. Barron brought up the interesting question of possible constitutional inability to withstand so-called normal blood pressures in etiology of left ventricular hypertrophy. This is a possibility which is difficult to rule out. Dr. Ben Clawson also feels that this factor may be responsible for some of the 5 per cent of Dr. Clawson's large series of left ventricular hypertrophies which had no clinical hypertension.

I should like to make one further remark concerning this paper. It would be quite unfair to Dr. Ikeda if I did not point out the fact that the pulmonary artery involvement in Case 3 was in reality quite inconspicuous and was not well brought out until special elastic tissue stains were made. Even then, only a relatively few areas were involved.

Dr. Ylvisaker, of Minneapolis, read his inaugural thesis, "Biopsy Studies of the Gastric Mucosa." Lantern slides were shown.

BIOPSY STUDIES OF THE GASTRIC MUCOSA

R. S. YLVISAKER, M.D.

Minneapolis, Minnesota

In 1945, we presented before the Medical Staff of the University of Minnesota Hospitals,[25] a review of the subject of chronic gastritis. At that time, we could find histologic data on only six cases of atrophic gastritis among the many hundreds of gastroscopic examinations which had been done previouly in the gastroscopy clinic. In other words, virtually all of the diagnoses of the various types of gastritis were based on gross decriptions of the gastric mucosa as seen through the gastroscope. We cited at that time the crying need for more histopathologic information to serve as an important foundation for these diagnoses.

Along with most gastroscopists, we have used Schindler's classification of the gastritide as a convenient outline of the gross appearance of the various forms of gastritis. This classification with descriptions was completely detailed in Schindler's original monograph "Gastroscopy."[20] This treatise, together with his later monumental work "Gastritis,"[21] has served as a tremendous impetus to the further study of gastritis as well as other conditions affecting the gastric mucosa.

Schindler, himself, has seen the need for more histologic data and has devised a method of obtaining full thickness biopsies of the gastric wall at laparotomy.[21] Unfortunately, this method does not lend itself to any large scale study of the gastric mucosa.

Hebbel[7,8,9] has continued his studies and has further clarified knowledge as to the detailed histologic appearance of gastritis as well as its incidence and its topographical distribution in otherwise normal stomachs, those with gastric and duodenal ulcer and those with gastric carcinoma. He questions the validity of the objections of Schindler, Necheles and Gold[22] to the use of surgically resected specimens for the study of gastritis.

On the clinical side, questions are being raised by many, notably W. L. Palmer and his group,[19] as to the significance of the gastritides in the production of symptoms. One senses this questioning in the, at times, rather lengthy philosophical dissertations on this subject in Schindler's monograph on gastritis.[21] In our opinion, this does not measurably detract from the wealth of factual data presented. Nevertheless, this healthy doubting has further pointed up the need for more correlation between the histologic and the gross appearance of the gastric mucosa.

Although the appearance of Benedict's operating gastroscope in 1948[1] was greeted with a good deal of caution by those interested in this field, it has gradually assumed an important position in the study of both diffuse lesions of the stomach such as gastritis and the diffusely infiltrating neoplasms, and the more localized lesions such as ulcer and circumscribed tumors. In 1950, Benedict[2] reported on the first sixty-three specimens which had been taken for biopsies without accident with his instrument. He called attention to the value of these biopsies in the differential diagnosis of gastritis and tumor and in the diagnosis and study of gastritis. This report was soon followed by that of Shallenberger, DeWan, Weed, and Reganis.[23] They report their experiences in sixty cases including cases of gastritis, gastric ulcer, malignancy, gastric polypi and marginal ulcer, detailing not only the advantages, but also the difficulties and limitations they had encountered. They concluded, among other things that the instrument is valuable and safe for general use and that indication for gastroscopy is indication for biopsy. In 1951, Benedict[3] reported further on his experience and included 203 biopsies thus far taken without accident. He did not report on his over-all experience with these cases, but detailed ten illustrative cases, in five of which positive diagnosis of carcinoma was established by biopsy and in five others diffuse gastric malignancy was excluded with reasonable certainty by gastroscopic examination and biopsy. He reported on the value of a positive biopsy finding but warned against the acceptance of a negative report especially in focal lesions. In 1953, Selesnick and Kinsella[24] reported their study of fifty-six gastroscopic examinations with mucosal biopsies in fifty patients in which only gastric mucosae that were interpreted as appearing normal or manifesting some form of gastritis were reviewed. They reported 91 per cent agreement with the pathologist in thirty-three cases showing gross evidence of gastritis, but only 60 per cent agreement where the gross diagnosis was that of a normal mucosa. In other words, the greatest disparity existed where the gastroscopist called the mucosa normal, overlooking pathology in 40 per cent of the cases. They also called attention to the fact that where a gross diagnosis of chronic hypertrophic gastritis was made, the pathologist usually found a normal mucosa.

In 1949, Doig[4] reported his use of a new flexible gastric biopsy tube devised by him. With this instrument a fragment of mucosa is drawn into a side opening in a flexible tube by suction and then cut off by a sharp blade. He found this method of value chiefly in the study of diffuse lesions such as gastritis, its main disadvantage being that it is a blind biopsy and usually reaches only one area—the greater curvature of the lower pars media. By 1952, Doig and Wood[5,6] had studied 112 cases of gastritis diagnosed by this method and compared them with groups of cases of duodenal and gastric ulcer. They found that the age of onset of both superficial and atrophic gastritis compared with that of gastric ulcer, but that the age of reporting was later for atrophic gastritis. They studied the symptomatology and course of gastritis extensively and concluded that this disease is a definite clinical and pathological entity, showing a recognizable, though variable and usually mild clinical picture. They also studied cases of subacute combined degeneration of the spinal cord and pernicious anemia and concluded that many cases without the characteristic blood picture could be diagnosed by finding true gastric atrophy on gastric biopsy.

In the United States, the method of Doig and Wood has been used extensively by Eddie Palmer.[10-18] In his clinic, the use of the suction biopsy is followed by gastroscopic examination so that he is able to see the area biopsied and study its gross appearance. In this way, he early obtained a remarkable correlation of gastroscopic and histologic findings, but some of his later reports admit to more frequent disagreement. He has studied the gastric mucosa in normal subjects, patients with duodenal ulcer, virus hepatitis, staphylococcus gastroenteritis, atrophic gastritis, postoperative gastritis, sarcoid disease, and chronic superficial gastritis. Apparently, one advantage of the suction biopsy over the biopsy taken with the Benedict operating gastroscope is that the fragment of tissue obtained is thicker and includes the muscularis mucosae and some submucosa.

The present report deals with the total gastroscopic biopsy experience in the gastroscopy clinic in the University of Minnesota Hospitals. The Benedict operating gastroscope has been used. This has been a co-operative undertaking. The gastroscopic examination and the taking of biopsies has been carried out by four different men, all well grounded in this procedure. I am indebted to Dr. J. B. Carey, Sr., Dr. James Myhre and Dr. J. B. Carey, Jr., for their part in this program. To some, this division of responsibility would appear to be a disadvantage. To us, it has been an advantage in that it affords a better over-all picture of the gross gastroscopic interpretation. Furthermore, in the few cases where more than one of the four persons has examined the same patient at different times, the agreement in interpretation has been remarkable. The histopathological studies were made by Dr. Robert Hebbel of the Department of Pathology of the University of Minnesota, who has had a large experience in the microscopic study of the gastric mucosa.[7,8,9] We feel that we have been fortunate in having Dr. Hebbel's co-operation and advice in this work.

A few words of explanation in regard to the instrument used might be pertinent. Its value in affording an opportunity to obtain biopsies of the gastric mucosa under direct vision is obvious. Certain disadvantages should be mentioned. In the first place, the instrument is definitely more cumbersome for the operator to handle and for the patient to tolerate than the Schindler instrument. This disadvantage can be overcome by being more deliberate with the examination. In the second place, it seems that the objective lens becomes more easily smudged and is less effectively "wiped off" on the posterior wall of the stomach, necessitating occasionally the removal of the instrument for cleaning and re-introduction, a procedure which in our opinion should be avoided. In the third place, it has been difficult at times to direct the biopsy forceps to the area of involvement. In a more or less diffuse lesion such as gastritis, this difficulty has not become too important. However, we have not been successful in obtaining biopsies from the antrum. On only one occasion did the biopsy specimen reveal antral mucosa, although the attempt to obtain specimens from the antrum has been made often. A few specimens showed the so-called transitional type of mucosa.

It is well to mention, too, that the specimens which we have obtained are often thin, including only parts of the mucosa without the muscularis mucosae. Then, too, it is not possible, even with several biopsies of the same stomach (we have made up to four) to study the whole gastric mucosa. We are studying merely samplings of the mucosa. The fact that the samplings are taken under visual control helps overcome this difficulty and affords an opportunity to study at least the area visualized.

Most of the examinations detailed in this report have been made during the past year, a few prior to that time. Although the series includes some focal lesions other than gastritis, it has been the distinct purpose of each investigation to study the gastric mucosa in its entirety. This study can, therefore, properly be called a study of the gastric mucosa as related to the appearance and incidence of gastritis. Except in a few instances, the operating gastroscope was used routinely during the past ten months. Since the series is small, we wish to designate this a preliminary report.

Eighty-four patients were examined. On one occasion the gastroscopic examination was unsatisfactory; in eight others, the biopsies were unsatisfactory; leaving seventy-five cases with satisfactory gastroscopic examinations and biopsies. In a few other cases, the gastroscopic examination was incomplete in some details, but enough visualization of the mucosa was obtained to make the correlation with the histologic findings satisfactory. There were eleven other individual biopsies which were unsatisfactory, but in these cases multiple biopsies had been taken, leaving other satisfactory biopsies in each case. Two patients were examined twice with biopsies, making a total of seventy-seven satisfactory examinations in seventy-five cases. There were thirty examinations with one biopsy each. Forty-seven with two to four biopsies each. Altogether 141 satisfactory biopsies were taken.

Two complications should be reported. These were complications of the gastroscopic examination, not of the biopsy taking as such. One patient developed a mediastinitis with subcutaneous emphysema of the lower cervical region. This subsided on antibiotic therapy after a short febrile course. The other patient developed severe esophageal pain and dysphagia, sufficient to require hospitalization. Protective anbtiotic therapy was given, and the symptoms subsided after a brief afebrile course. Both of these cases had required removal and re-introduction of the gastroscope.

Histologically, each sample was classified as showing normal mucosa, superficial gastritis, or atrophic gastritis. In order to be classified as normal, the sections were required to show intact glandular elements with a normal component of specific cells and little or no cellular infiltration in the stroma. Those with superficial gastritis showed excessive cellular infiltration in the

stroma but no change in the glandular elements including no significant loss of specific cells. We do not feel that any one case of superficial gastritis can be stated as being acute or chronic from its histologic appearance. Repeated biopsies over a period of time would be needed to determine this. Those with atrophic gastritis included any that showed loss or change in the glandular elements, i.e., loss of specific cells and/or total glandular substance, and/or metaplasia of the glandular elements. No attempt was made to distinguish between atrophic gastritis and gastric atrophy nor do we believe any clear-cut distinction exists.

Tables I, II and III show our over-all experience based on histologic diagnoses. No attempt at statistical analysis has been made because the series is small. Only certain obvious trends can be shown. Percentage figures are given for the larger totals. There were fifty-three men and twenty-four women. Grouped according to ages, there were four men from thirty to thirty-nine, nine from forty to forty-nine, ten from fifty to fifty-

TABLE IV.

Histology	Gastroscopy	No. Cases

	Probable carcinoma	1

nine, twenty-one from sixty to sixty-nine, seven from seventy to seventy-nine, and two over eighty. Among the women, there was one between twenty and twenty-nine, three between thirty and thirty-nine, four between forty and forty-nine, seven between fifty and fifty-nine, five between sixty and sixty-nine, three between seventy and seventy-nine, and one over eighty.

Of the total group, forty-five had free HCl in their gastric secretion, twenty-three had achlorhydria, and nine had no gastric analysis performed. All the achlorhydrias were histamine achlorhydrias, many having repeated determinations. Histologically, thirty-six showed normal mucosae, eight superficial gastritis, twenty-eight atrophic gastritis, four superficial gastritis on one or more samples and atrophic gastritis on other samples from the same stomach and one had adenocarcinoma on a single biopsy from a tumor. The tables clearly demonstrate the usual preponderance of atrophic gastritis in the group with achlorhydria. Whereas, those with free HCl in their stomach contents showed twenty-seven normal mucosae on biopsy and only eleven with atrophic gastritis (including two with both superficial and atrophic), those with achlorhydria showed only three normals but eighteen atrophic gastritides. Seven out of eight of those with superficial gastritis had free HCl in their stomach contents. Only two out of the eight cases of superficial gastritis were men, whereas the latter accounted for twenty-four out of thirty-two cases with atrophic gastritis. None of the women with free HCl showed atrophic gastritis and none of the women with achlorhydria had normal mucosae. There was one case of proven pernicious anemia and one of subacute combined degeneration of the spinal cord with a normal blood picture. Both showed atrophic gastritis on gastric biopsy.

Grouped according to ages, fifty-six (72.7 per cent) of the seventy-seven patients were over fifty years of age. Of the thirty-two patients showing evidence of atrophic gastritis (including the four which showed both superficial and atrophic gastritis) only one was under forty years of age and three under fifty; or 90.6 per cent were over fifty years of age. Conversely, of the fifty-six persons in the series over fifty, 51.8 per cent had evidence of atrophic gastritis and 60.7 per cent had evidence of one type of gastritis or the other or both, while only 14.3 per cent of those under fifty showed atrophic gastritis and 28.6 per cent one type of gastritis or the other or both. This high incidence of atrophic gastritis in the older age group agrees with the findings of Hebbel[8] and others.

Correlation of gross gastroscopic findings with the histologic findings brought out some very interesting results. Table IV shows the gastroscopic appearance in thirty-six cases with normal histology.

TABLE V.

	Polypi with red mucosa	1
	Probable carcinoma	1

The cases with hypertrophic mucosae will be commented upon later. As it will be seen, these cases should probably henceforth be classified as normal mucosae. The case of probable carcinoma turned out actually to be carcinoma and was missed by biopsy. This case points up the warning of Benedict previously mentioned, that a negative biopsy in a focal lesion should not be accepted as a final diagnosis. The one case diagnosed as atrophic mucosa, then, becomes the only error in gastroscopic diagnosis in this group. If allowance is made for the possibility that the atrophic area might have been missed on biopsy (even though three areas were biopsied in this case) the correlation between gross gastroscopic and histologic findings in this group becomes remarkable.

Table V shows the gastroscopic appearance in eight cases diagnosed as superficial gastritis histologically.

It will be noted that no diagnoses of chronic superficial gastritis were made on gross appearance in this series. There were probably two reasons for this. In the first place, as time went on there was an agreed upon tendency among the four coöperating gastroscopists to describe what was seen rather than to make diagnoses. In the second place, none of the cases in this series showed the mucosal exudate or sticky mucus thought to be characteristic of chronic superficial gastritis. In this group, then, there were four mistaken diagnoses and four cases in which a raised, white area, the hyperemic edematous mucosa, and the increased high-lighting were not considered sufficient evidence by the gastroscopist to make a definite diagnosis, but proved to be the only surface indications of an underlying, superficial gastritis.

Table VI shows the gastroscopic appearance in twenty-eight cases of atrophic gastritis.

It will be noted that there were fourteen cases in which the gastroscopist definitely agreed with the histologic diagnosis, eight cases in which he definitely

*This signifies one type of gastritis in one sample and the other type in another sample from the same mucosa.

missed the diagnosis and called the mucosa normal, one case in which he called the mucosa hypertrophic (the only case of hypertrophic mucosa showing gastritis histologically), one case with multiple small, irregular ulcers—probably a true case of ulcerative gastritis, one case in which the biopsy was taken from the rim of a gastric ulcer, one case of postoperative gastritis, one case with benign polypi and a very red mucosa, and one case thought to be carcinoma by the gastroscopist. The rather large number of normals in this group tends to confirm the finding of Selesnick and Kinsella[24] and others that the greatest disparity between the gastroscopic appearance and histologic findings lies in the gastroscopist missing gastritis when it is definitely present in a fairly large number of cases.

The case thought to be carcinoma was one in which the patient had bone lesions interpreted as being metastases, but who died elsewhere without an autopsy being performed.

Table VII indicates the gastroscopic findings in four cases found to have both superficial and atrophic gastritis histologically on different samples by biopsy. It will be seen that various types of gastritis likewise were found gastroscopically.

If we reverse the situation and investigate the various histologic diagnoses when definite gastroscopic diagnoses had been made, equally interesting results are obtained. Table VIII tabulates these results. It will be noted that only those cases are tabulated in which a definite diagnosis was made gastroscopically.

Equivocal diagnoses or those with merely descriptive accounts without a definite gastroscopic diagnosis are not included. Here again, when a diagnosis of a normal mucosa was made gastroscopically, a considerable number of atrophic gastritides were overlooked; whereas, when a diagnosis of atrophic mucosa was made, a good correlation with atrophic gastritis histologically is seen. Again, the cases which were diagnosed as showing hypertrophic mucosa all proved to be normal histologically except one. It should be explained in this connection that the fragments of tissue obtained by this method of biopsy are often thin and the pathologist was unable to measure the full thickness of the mucosa in the great majority of cases. A true evaluation of the presence or degree of hypertrophy was, therefore, not possible. However, it can be stated that none of the sections in the cases designated as hypertrophic by the gastroscopist showed any of the other evidences of gastritis histologically, nor was there any visible piling up of the glandular elements. We shall have to agree with Selesnick and Kinsella,[24] therefore, that on the basis of our findings, cases with the usual evidences of hypertrophy gastroscopically should be called normal and that this finding should be considered a normal variation probably related chiefly to the functional state of the muscularis mucosae. It might appear that cases showing hypertrophy gastroscopically are more apt to be normal histologically than those that are normal gastroscopically.

TABLE IX. DISTRIBUTION OF GASTRITIS IN ULCER CASES

Type of Ulcer	Total	Type of Mucosa				
		Normal	Superficial Gastritis	Atrophic Gastritis	Normal & Gastritis	Mixed Gastritis
Duodenal	9	6	0	1	2	0
Gastric	8	2	0	4	2	0
Gastric and duodenal	2	2	0	0	0	0
Pyloric	5	3	0	1	1	0
Duodenal and Stomal	1	1	0	0	0	0
Stomal	1	1	0	0	0	0
Total	26	15	0	6	5	0

Certain other features of this series should be mentioned. There were twenty-six cases of peptic ulcer: nine duodenal, eight gastric, two gastric and duodenal, five pyloric, one duodenal and stomal, and one stomal. The five pyloric ulcers included those which might be either just pre-pyloric or post-pyloric, most cases being difficult to determine roentgenologically.

Table IX shows the type of mucosa found histologically in the body of the stomach in the various types of ulcer.

The group is too small to make any comments but, in general, the findings agree with those of Hebbel[7] that gastritis is common in the body mucosa in cases with gastric ulcer and unusual in cases with duodenal ulcer.

In regard to the distribution of the gastritis, in the case of atrophic gastritis we shall have to agree again with Hebbel[8] that the lesions show a wide range between focal and diffuse. The only exception, as he points out, lies in those cases in which the greater curvature is involved. When this is the case, according to him, the lesion is more apt to be diffuse. In our series, only seven cases, among those with multiple biopsies, were found which showed atrophic gastritis on the greater curvature. In all of these, atrophic gastritis was found in all other areas sampled. On the other hand, atrophic gastritis was found on the lesser curvature in nine cases, and in only five of these were all other areas similarly involved.

Table X indicates the types of symptoms complained of in the cases without ulcer, gallbladder disease, or cancer. Again, the series is too small to draw any conclusions. The only symptoms which seem to be more common in cases with gastritis than in the normals are pain after eating and flatulence. On the other hand, the asymptomatic cases fall almost entirely in the gastritis group. In other words, no definite symptom complex for gastritis is present.

Summary and Conclusions

This report has presented a review of the literature in regard to histologic findings by gastric biopsy in gastritis with special reference to its correlation with the gastroscopic appearance, and has detailed the total gastroscopic biopsy experience at the University of Minnesota. In the latter work, the operating gastroscope of Benedict was used. Some of its advantages and disadvantages as well as those of the type of biopsy obtained have been pointed out. Seventy-seven gastroscopic examinations with 141 biopsies were done.

Although the total number of cases is not sufficient to allow for any final conclusions, some very definite trends are brought out.

1. The well-known increased incidence of atrophic gastritis with age and in cases with achlorhydria is confirmed.

2. The correlation of gastroscopy with histology in cases which proved to be normal histologically is found to be excellent if cases showing hypertrophic mucosae gastroscopically are included with the gastroscopic normals. The finding of normal mucosae microscopically in those with hypertrophy gastroscopically agrees with the finding of Selesnick and Kinsella. We are inclined to agree with their suggestion that mucosal hypertrophy is due to a functional derangement of the muscularis mucosae and does not represent a true gastritis.

3. A definite disparity in the correlation of gastroscopy with histology in cases showing atrophic gastritis histologically is confirmed. In other words, no surface evidence of an underlying atrophic gastritis was found in a considerable number of cases. Conversely, when atrophic mucosa is seen gastroscopically, atrophic gastritis will be found histologically in a high percentage of cases.

TABLE X. SYMPTOMS IN CASES WITHOUT ULCER, GALLBLADDER DISEASE, OR CANCER

Symptoms	Normal	Gastritis
Pain after eating	3	7
Flatulence	1	4
Asymptomatic	1	8
Asymptomatic—(post-gastrectomy)	0	2
Vague epigastric distress	3	3
Abdominal pain other than epigastric	4	6
Nausea and/or vomiting	4	2
Typical ulcer distress	2	3
Weight loss	1	3
Nervousness	0	2
Spells of violent epigastric pain	1	0
Pyrosis	0	1
Weakness	2	1
Alternating constipation and diarrhea	0	1

4. Superficial gastritis shows a comparatively low incidence and a varied gastroscopic picture in this series. Surface exudate or sticky mucus does not appear to be an essential finding.

5. Hebbel's finding of the unusual occurrence of atrophic gastritis in the body mucosa in cases of duodenal ulcer as well as its common occurrence in cases with gastric ulcer is supported in this series.

6. Likewise, Hebbel's finding of a wide range indistribution of gastritis from focal to diffuse, and the definite tendency for it to be diffuse when the greater curvature is involved, finds support.

7. No characteristic symptom complex for gastritis is found.

Discussion

Dr. James B. Carey, Minneapolis: I appreciate the opportunity of participation in this study with the Benedict biopsy gastroscope. When the flexible gastroscope was first introduced in this country by Benedict in Boston in 1934, then by Schindler in Chicago in 1935, and in this territory in 1936, the classification of gastritis suggested by Schindler was accepted, i.e., superficial gastritis, atrophic gastritis, hypertrophy gastritis, and gastritis of the postoperative stomach. This classification of Schindler's was not unequivocally substantiated by direct histologic evidence. It was based on objective gastroscopic appearance of the gastric mucosa. The only substantiation was by histopathologic studies of autopsy or surgical material from individuals different from those examined gastroscopically.

Two methods for obtaining biopsies from the mucosa of the stomach are now being used; one is with the flexible instrument in which a biopsy forceps is incorporated and by which the part of the stomach from which the specimen is obtained may be seen; the other method is that of Doig and Wood, of Australia, which is blind. A tube with an open end, a section device, and a cutting obturator is passed into the stomach. The specimen is usually of the greater curvature of the stomach opposite to the orifice of the esophagus. Later the part of the stomach from which the biopsy was taken may be identified through the diagnostic gastroscope. Obviously, two passages of instruments is required.

Before biopsies of the stomachs of living patients were possible, some of us were beginning to be a little skeptical about superficial and hypertrophic gastritis. The small number of patients presented by Dr. Ylvisaker stresses this doubt. The original concept, based on Faber's work, was that superficial gastritis might accompany several infectious diseases, and, if repeated, could be the basis for permanent atrophic gastritis. Faber's specimens were obtained after introducing formalin solution into the stomach as soon as possible after death in order to inhibit postmortem disintegration. These studies supported the gastroscopic diagnoses of superficial and atrophic gastritis. But interpretation of changes apparently indicative of hypertrophic gastritis has been uncertain. The latest work on this subject by Col. Eddy Palmer of Walter Reed Hospital does not support the concept of hypertrophic gastritis as described by gastroscopists as pavement mucosa, cobblestone, thick, and other terms. Palmer did say, however, that the gastroscopic appearances were truly seen, but that the clinical significance of such observations was dubious.

The other question is whether all changes called atrophic gastritis are actually gastritis, that is, inflammatory. Some of the changes may be nutritional or senile, related to degeneration of other parts of the body. Also, the gastric mucosa may differ from person to person, as do other body structures; for instance, the skin. In other words, what may appear to be atrophy or hypertrophy may actually be normal for the particular individual.

I believe that, from knowledge derived from biopsies of gastric mucosa, the orderly classification of Schindler must be modified. For instance, English and Australian workers have virtually abandoned the term hypertrophic gastritis.

Dr. L. G. Rigler, University of Minnesota: It is very difficult and possibly unwise to make a diagnosis of gastritis from x-ray examination of the stomach. I did see a case of true hypertrophic gastritis just this morning—a seventy-two-year-old doctor who came into the hospital with a very severe gastric hemorrhage. Dr. Varco did a subtotal resection of his stomach. He had very large folds; not only that, but the gastric glands penetrated well into the muscularis although there were no actual points of bleeding. Many of the cases with large folds are not gastritis, simply redundancies of the mucosa.

Dr. Ylvisaker, in closing: I wish to thank Doctor Carey and Doctor Rigler for their discussions. We plan to carry on this study over a period of years with the hope especially of obtaining more information in regard to the development of gastritis. Doctor Hebbel tells me that he is interested in this phase of the study. In regard to the matter of hypertrophic mucosa, while we have not found any true hypertrophic gastritis in our series, we feel quite certain that there are cases of so-called giant rugae which should be classified as true hypertrophic gastritis. These are not at all common.

The meeting was adjourned.

Robert E. Priest, M.D., *Secretary*

Meeting of May 12, 1954

This meeting, at which the retiring President read his Address, was held at the Minneapolis Club on Wednesday evening, May 12, 1954. Dinner was served at 7 o'clock and the meeting was called to order by the President, Dr. Regnier, at 8:15 p.m.

There were fifty-two members and five guests present.

No business was transacted at this meeting, and minutes of the April meeting were not read.

RETIRING PRESIDENT'S REMARKS

Dr. E. A. Regnier: My fellow members of the Academy, you have done me a great honor in electing me your president in the past year. For this privilege, I assure you my sincere gratitude for your respect and confidence. It has been a pleasure to serve, and its reward, namely, your confidence, I shall always cherish. At this time I want to thank the members who have served with me on the various committees. The co-operation of the Executive Committee, the Membership Committee, the Program Committee was most gratifying. I want to commend particularly the Program Committee for furnishing the excellent programs which we have enjoyed throughout the past year. My sincere thanks to all of you, and particularly to our secretary, Dr. Robert Priest.

This Society is now completing its seventy-seventh year, and it has reached a stage of maturity, whereby it should occupy a position of great prestige in this community. Your present officers have served an added six months due to the change voted by the Academy last December. The presidential meetings are to be held alternately at the Minneapolis Club and the Minnesota Club.

To our new president, I extend greetings and best wishes for continued progress toward our objectives and give assurance of my full co-operation.

As you know, we have increased our membership to a capacity of 125 men when the roster is filled. This, I believe, is a far-reaching step and in my opinion should be further amended. It is my opinion there should be no limit to the number of memberships in this Society, if the candidates could meet the requirements of the organization.

The Academy derives its strength, not from a numerical role, but from intellectual and cultural qualities and moral attainments. We should be truly representative of the medical fraternity before society. In other words, the Minnesota Academy of Medicine should occupy and deserve a high position in public relations and medical ethics throughout the Northwest.

One of my recommendations to this Society is that next year's Executive Committee sponsor a committee on public relations and inter-medical relations. This committee should be very carefully selected, and it should concern itself with medical education, inter-relations of the public with medicine and promotion of more wholesome respect and co-operation between medicine, as practiced by specialists and general practitioners. This committee should also concern itself with socialistic trends in medicine and should be ready and free to voice an opinion in rebuke or approval of any group from the level of a county society to the American Medical Association. If every state had an organization of men with mature judgment and the fortitude to function fearlessly and justly, we would not have to apologize or alibi for endorsement of the Bricker Amendment in Congress, by representatives of organized medicine. And I think if such a committee was supported by the opinion of the Society, we could forestall the possibility of a pseudo-scientist going unchallenged in exposing the indecency of his mind under the guise of giving a scientific report.

This Society has been called a dining club of professional men. True, this caption covers one phase, and a very essential one, of our purpose but surely only a limited one. The social and convivial aspects of this Society are second to none and I am sure, cherished by every member. However, our fundamental purpose is to band together to promote higher standards of medical ethics and practice of medicine through education, mutual and fraternal assistance, to the end that our noblest instincts will be guided by the Light of Truth.

It is true, we have very limited funds, but ways and means should be implemented to increase these funds. I submit to you that no member of this Society would be hurt by an annual assessment of $10 to $25 toward raising a scholarship fund. This assessment should be one which would raise $1200 to $1500 annually. It could be augmented by voluntary donations and by funds given as memorials by friends of our departed members if our members were solicitous of such. I am leaving a memorandum with our secretary to the effect that these matters be placed before the Society through the Executive Committee early next year. The members of the scholarship and educational committee could make recommendations to the Academy and the entire membership could decide on what fellowship to sponsor and how often this fellowship could be supported. It would be known as the Minnesota Academy of Medicine Fellowship at the University of Minnesota. Such a small sacrifice by each member would accrue to the honor of our Society and give its individual members a sense of pride and justification in an act accomplished, in fostering not only an excellent dining club, but a legacy to posterity in a scholarship fund. By establishing and supporting a fellowship at the University of Minnesota the influence of the Academy would become a living memorial to its founders. Our compensation would be the realization of the furtherance of the art and practice of a noble profession. An assessment sufficient to raise $1,000 plus the interest on our bonds plus memorial contributions and voluntary donations should support a fellowship every three years until our membership grows to a point where a year or biennial endowment could be

History of Medicine in Minnesota

THE PIONEER DOCTORS OF CHIPPEWA COUNTY
PRIOR TO THE YEAR 1900

LEON G. SMITH, M.D.

Montevideo, Minnesota

(Continued from January, 1955, issue)

From a civic standpoint, his most notable achievement was that of inducing the Milwaukee Railroad to move its division headquarters to Montevideo. It is generally acknowledged that it was largely due to his foresight, energy and persistence in working upon the railroad officials that this was finally accomplished in July, 1893. In consequence, Montevideo occupied one of the most important railroad positions of any town in western Minnesota. The round-house, car-repair shops, freight yards, stock yards and dispatcher's offices brought many families to the town, and supplied a payroll which was a tremendous factor in its growth and development.

From a combined civic and medical standpoint, almost as notable an accomplishment was the campaign to build the Montevideo Hospital. This would probably have been built eventually in any case, but Dr. Rogers is given the credit for being the instigator of the project, and the moving force in carrying it to its completion in 1910.

He did not live continuously in Montevideo. For a few years he practiced in Minneapolis, in 1890 becoming associated once more with his old friend and preceptor, Dr. Hoegh, who had moved there from La Crosse.

Dr. Rogers was always good newspaper copy. Quoting the *Montevideo Leader* of March 25, 1887: "A series of articles, published by the *Commercial* man, uncomplimentary to Dr. C. E. Rogers, resulted in the latter soundly slapping the former's face last Saturday night." He was undoubtedly a better than average surgeon for his day, and as a result was widely called in consultation. The newspaper files, during these years, alluded to these calls frequently and described several of the difficult operations that he performed. This is not noted in any derogatory sense, as news stories about doctors and their achievements seem to have been entirely permissible in those days.

Even when he was practicing in Minneapolis was this true. I quote the *St. Paul Dispatch* of May 18, 1894: "A dislocated neck, twisted back in to proper shape, and medical science has another remarkable event to recall.

"One of the most interesting incidents, in the experience of medical men of the Northwest, happened in Minneapolis yesterday. Indeed, it will be numbered among the remarkable events in the medical history of the world. A man whose neck had been dislocated by a fall, causing his head to be twisted almost one-fourth around, and with a forward tilt, walked into the office of Dr. C. E. Rogers, and asked to have the kink straightened out, not seeming to realize the serious character of his case. It is rare that such a dislocation occurs without paralysis, due to pressure on the spinal cord, and the physician saw he had a truly wonderful case before him. The patient, Thos. H. Golrick, of Keegan's Lake, was put under an anaesthetic and the neck gradually twisted back to its right position. As it sprang back into place, a distinct click was heard, and, suddenly, respiration ceased. The head fell to the other side, the neck became perfectly lax, and general collapse seemed to have taken place. Golrick's position, however, was quickly changed, his head raised and his tongue held so it could not obstruct the air passage. Quickly, respiration began again, and he slowly came from under the influence of the anaesthetic. When he was able to talk, he could tell nothing of the terrible experience he had been through, and was quite surprised when it was related to him. After a few minutes, he started for home, apparently as well as before the accident."

In 1897, Dr. Rogers bought part ownership in the Riverside Sanatorium for Tuberculosis and Lung Diseases, located in St. Paul, where the "pneumo-chemic system of treatment for consumption, bronchitis, catarrh, asthma and hay-fever" was used.

In July, 1898, he and his family moved back to Montevideo where he spent the rest of his life.

In 1904, he nearly lost his life. Again I quote from the *Montevideo Leader* of January 15: "Last Saturday night, Dr. C. E. Rogers went home, feeling very poorly. Next day, he was considerably worse, the indications pointing strongly toward appendicitis. Sunday night he suffered a more serious attack, which confirmed the diagnosis of Dr. Zimbeck and Dr. Herbert Rogers. Dr. Hoegh was asked to come up from Minneapolis on the next train, and Dr. Stratton of Granite Falls, Dr. Titus of Sacred Heart and Dr. La Rue of Appleton were also called. All came except Dr. La Rue, who did not receive word in time. Monday morning, Dr. Hoegh performed an operation, assisted by the other physicians present. It was found to be a very serious and complicated case, requiring an operation also for hernia. The operation was successfully performed, however, and the patient got along well until Wednesday morning, when he had a bad time, due to coughing and vomiting. That evening he was very low, indeed, but the symptoms grew more favorable through the night and yesterday, and his friends now have hopes for his complete recovery." And recover, he did.

Dr. and Mrs. Rogers had six children, one son and five daughters, of whom three, including twin girls, died in infancy or childhood. The son, Herbert W. (or Bert, as he was always called) attended the Minneapolis and Montevideo public schools and studied medicine at Northwestern University in Evanston, Illinois, joining his father in practice in 1903. Only three years later, he died as the result of a ruptured appendix.

As was to be expected, the loss of his only son, reared in the atmosphere of a doctor's home, trained in the study of medicine, and associated with him for three years of practice, was a terrific blow to Dr. Rogers. However, he carried on his work as usual and it was after Bert's death that he successfully pushed to completion the hospital project.

In 1911, Dr. Carl M. Johnson, a young doctor, just out of the University of Minnesota Medical School and a year's interneship in St. Barnabas Hospital in Minneapolis, became associated with him.

Upon December 3, 1912, his death occurred quite suddenly, from "angina pectoris." His wife survived him for several years, and his two daughters, Gertrude Titus and Jean Hubbard, are now living in San Diego, California.

One last quotation about this remarkable man taken from the *Montevideo*

Leader of December 6, 1912: "In the death of Dr. Rogers, our community loses one of its most worthy and public-spirited citizens, the medical profession one of its most competent and successful practitioners, and his family and friends a loving, generous and whole-souled husband, father and friend."

Shortly after Dr. Rogers came to Montevideo, the first Medical society was organized. September 28, 1883, a news item stated: "The physicians along the line of the H. and D. (Hastings and Dakota was the name of this division of the Milwaukee Railroad) met at Montevideo September 13 and organized a society called the Western Minnesota Medical Association, such society to meet again at Montevideo December 4, at 9 A.M." The records of this society must have been lost, including the roster of its members, and it is not until 1903 that there is any further mention of a medical organization. At that time Chippewa, Lac qui Parle, Yellow Medicine, and Renville Counties joined and formed the Camp Release District Medical Society as a component group of the Minnesota State Medical Association. The earlier records of this society have also been lost, so, at least locally, no roster of the charter members is available.

In 1883, **Dr. Galen D. Moyer** located in Montevideo, qualified and licensed both as a dentist and a physician. He was born in Sanborn, New York, and received his dental education in the College of Dentistry of the University of New York, graduating in 1879. He went to Pau, France, after graduation, being associated for a year there in dental practice with a Doctor Edwards. He returned to the United States in 1880, and studied medicine at the New York College of Medicine, graduating in 1883. His older brothers, Lycurgus R. and Lloyd G. Moyer, had come to Montevideo several years earlier and had taken a prominent part in starting and building up the new town. Since two sisters had also moved here, it was the natural thing for Dr. Moyer to follow suit immediately after graduation.

While he was carried in the records of Polk's Medical Register for many years as a Doctor of Medicine, all his professional cards and the news items about him during this period indicate that he actively practiced dentistry, but did no medical work except in the role of anaesthetist. He married a teacher in the Montevideo schools, Harriet Page, April 29, 1891, to whom two children, Margret and Galen Dana, were born.

He moved to Minneapolis in 1911, though a year or two later, his name is noted as vice-president of the V. B. Dental Club of St. Paul. Shortly thereafter he moved to Wisconsin, having his home in Spring Brook, but his office in Hayward, where he practiced until retirement in 1938. He then moved back to Chippewa County, buying the small farm across the river from Granite Falls where he died in 1940.

His daughter, Margret, now Mrs. George Halpin, lives in Minneapolis and is the owner of the well-known and exclusive women's apparel store, "Harolds."

In the late eighties, two new names appear, but so briefly as to merit small mention only. In the *Montevideo Commercial* of August 27, 1886, **Dr. Berens** was listed as "Physician, Surgeon, and Accoucheur," but this is the only time his name appeared. In issues of the same paper from January 7, 1887, to March 18, 1887, was a professional card reading **"Mrs. Dr. J. E. Hull**, Physician and Midwife," the wording of which would indicate she was an unlicensed practitioner.

In this connection, I feel some mention should be made of the Indian shows of the 1880's and 1890's. Many people waited for the annual visit of these shows and combined the pleasure of watching their entertainment with the business of laying in a year's supply of the various liniments for man or beast, and other medications offered. Probably the best known of these itinerant troupes in Western Minnesota was the Kickapoo Indians.

They were from a Kansas and Nebraska tribe, and the euphonious sound of the name Kickapoo, made it particularly desirable as the title of a medicine show or the name of a tonic.

Dr. Wallace Jason Collins was the next regular physician upon the local scene, and, though his stay was for only a few years, he seems to have developed a rather large practice in that short time. His early history is not very complete, but information obtained from his step-daughter, would indicate that he was born in Gardner, Maine, about 1850. She remembers hearing that his father was a sea-captain. He graduated from Bowdoin College in Brunswick, Maine, in 1886, and was licensed in Minnesota March 25, 1887. His first location was in Dawson, Minnesota, but he moved to Montevideo July 20, 1888.

One of his first patients here was Joseph Melchior, who died in September of that year. The acquaintance, made with Mrs. Melchior at the time, developed further because in the *Montevideo Leader* of April 10, 1891, we find the following: "Dr. Wallace J. Collins and Mrs. Mathilda Melchior were matrimonially united Thursday evening last week. The event was a quiet one, and the happy couple took the morning train to the Twin Cities, where they passed a few days. They are now at their home on Third Street."

Newspaper items report his having "operated upon a young man named Ekstrom for hare-lip, with a good result, performing the operation in the Sparta House."

There is also an account of an accident which was a frequent one in those days: "Jas. Franzen of Appleton sustained a terrible and perhaps fatal accident. In sliding off a grain stack, he struck on the handle of a pitch-fork, the handle perforating his rectum and bowel. Dr. Collins was called and took him at once to St. Anthony Hospital in Minneapolis."

Dr. Collins' marriage broke up, with his wife leaving him in 1894. Late in 1895 his card disappeared from the Montevideo papers. He went back East, and his named appeared in Polk's Register from Gardner, Kannebeck County, Maine, in 1896. From 1903 he was listed from Westfield, Massachusetts until his death there, November 23, 1932, from angina pectoris.

Dr. John C. Tillman lived in Chippewa County for several years. He never practiced medicine here, though he did in Germany. The following was his obituary: "Died, at Montevideo, Minnesota, June 11, 1896, Dr. John C. Tillman, aged 82 yrs., 11 mos., 24 days. He was born at Colon, (probably Cologne) on the Rhine, January 19, 1813. He graduated from the University of Bonn, served in the German army, and practiced medicine in Germany for fifteen years, before coming to the United States in 1854. He lived, for a long time, in St. Peter, Minnesota, but for the past seventeen years, has lived in or near Montevideo. He has been married twice, and leaves a widow, with six of her children and two by his first wife."

C. S. (Spurge) Tillman was his son and lived most of his life in Montevideo. Along with his other work, he prepared and dispensed Tillman Oil, which was a rather famous medication in this area in the early part of this century. Undoubtedly prepared according to a formula of his father's, it was a powerful irritant, probably composed mostly of croton oil. Applied after pricking the skin with a multiple puncture appliance, it certainly "drew the poison out" in the form of numerous pustules.

Dr. Tillman's grand-son and grand-daughter still live in Montevideo.

The next name encountered is **Dr. Russell Stewart Bacon.** Here is a man who ranks high in importance in our list of pioneer physicians. An excellent doctor, he was public-spirited, and he took an active part in many civic enterprises. His fifty-one years of continuous, active practice in Montevideo make him second only to Dr. M. A. Burns in length of service to his community.

He was born May 28, 1859, the son of Mark and Emeline Bacon, at Elroy, Wisconsin. His mother died when he was four, and his father died when he was eight years of age. From this time on, he made his own way with the help of family friends. He worked his way through elementary school and graduated from high school in Mauston, Wisconsin, in 1880. He taught school for a time at Cottage Grove, a small town near South St. Paul, and studied medicine with a doctor there. He then attended Rush Medical College in Chicago, paying his way by working on the street-car lines, graduating in 1885. He came to Minnesota at once and established his first practice in Dawson in 1886, but moved to Appleton the next year. There he remained for two years. On April 11, 1899, he came to Montevideo and set up his practice, in which he remained active until 1940.

There were three excellent and active doctors in Montevideo when he arrived, Drs. Murphy, Collins and Rogers, but he soon began to get his share of business, and newspaper items in the succeeding years frequently concerned him. I quote: "Dr. Bacon has had several calls to Milan of late. On every visit, he finds many patients awaiting him, and on one trip, there were seven patients at one house, who were brought in from the neighborhood." On March 6, 1891: "Dr. Bacon drove to Clarkfield during a blizzard Tuesday night. He spent the greater part of the night wandering around on the prairie, but finally reached his destination in safety." On October 8, 1897, an account of probably the first x-ray in the county: "On Tuesday, in Dr. Bacon's office, Roentgen rays were turned on Paul Falkenhagen's leg, broken some time ago, and a skiagraph taken. H. L. Olson developed the skiagraph."

I quote the next item, as much for the rhetoric employed as for its historical significance, from the *Montevideo Commercial* of December 8, 1893: "Married by Rev. Morse, Thanksgiving evening, at the residence of the bride's parents at Cottage Grove, Minnesota, Dr. R. S. Bacon and Alice Gallinger. Our popular townsman, Dr. Bacon, not satisfied, as most mortals would have been, with ordinary Thanksgiving cheer, reaches out toward the hymeneal altar and snatches therefrom one of the fairest flowers of Cottage Grove, and claims her as his own. Surrounded by many witnesses, he plights his faith to one, who for many years, has been the idol of his heart, and unites his future to the brave and noble army of benedicts. That our genial doctor has done well, all will hope; that he has done wisely, none will question; that his future will be bright and happy all will pray. And now that he has returned to Montevideo, bringing his bride with him, a host of friends will meet them with hearty congratulations and kindly wishes that this crowning act may ennoble, enrich and beautify their united lives."

In addition to Dr. Bacon's extensive practice, he found time for many other activities. He served on the draft board during World War I and was a member on the school board from 1909 to 1919 and secretary of the U. S. Pension Board 1890-1929. He was also a member of the board of directors of the Riverside Sanatorium 1917-1937, and director of several banks at various times. He was a member of the Masonic Lodge since 1889, serving as Worshipful Master one year; a member of Damascus Commandery of Knights Templar of St. Paul since 1890; and a life member of the Camp Release District, Minnesota State and American Medical Associations.

He was confirmed as an Episcopalian in 1882, at Basswood Grove, Minnesota, but during his residence in Montevideo, attended the Congregational Church.

He kept abreast of medical times by frequent attendance at meetings and clinics. Dr. Bacon took extended courses of post-graduate work at New York University in 1892, again in 1896, and spent most of the winter of 1900 at New Orleans Poly-Clinic. Also, for a time in 1899, he went to Minneapolis every Saturday and worked in surgery as an assistant to Dr. Fred Dunsmoor in Asbury Hospital.

He retired from active practice in September 1940 at the age of 81, and his death occurred at the Montevideo Hospital only a few months later. His wife, two sons and two grandsons survived him, but Mrs. Bacon and one grandson, Richard, have died since then. His older son, Guy S., lives in Cottonwood, Minnesota, and the younger, Arthur, with his wife, resides in Dr. Bacon's old home in Montevideo.

Dr. Bernhard Lambrechts was educated both as a Doctor of Medicine and as a veterinarian. He was born in Christiania, Norway, April 15, 1828. Under some form of government subsidy, he received his education, with expenses paid, at Wittenberg, Germany, and Copenhagen, Denmark, graduating from both medical and veterinary school. He returned to practice medicine in Christiania and conducted a free clinic during part of his time (for an hour in the forenoon and an hour in the afternoon). According to his son, from whom I obtained this information, this was objected to by the aristocracy, and, as a result, Dr. Lambrechts emigrated to America in 1867, locating in southeastern Minnesota. His practice covered a huge territory extending from La Crosse, Wisconsin, to Northfield, Minnesota. In 1870, he spent some time in St. Louis, doing post-graduate work. In 1872, he moved to a farm a mile east of Willmar, in Kandiyohi county, again practicing medicine over a large area, extending from New London and Norway Lake to Benson and Montevideo. During this period, he served as coroner of Kandiyohi County for several terms. In 1891, he sold his farm and moved to Montevideo, but after locating here did no medical work and practiced veterinary medicine and surgery only. He was a member of the State Veterinary Board for several years. He was able to speak four languages fluently, Norwegian, German, French and English.

In 1904, he moved to East Granite Falls, where he died a year later.

His wife's name was Marie Muller, and there were three children: a son Barney, a daughter, Froides and a son, Thorfin, who studied Veterinary Medicine and practiced it all his life in Montevideo until his death in 1950. Thorfin's widow lives in the old Lambrechts home on North Second Street. The mother passed away in 1888, and Froides died in Illinois two years ago. Barney is living in Twin Brooks, South Dakota.

(To be continued)

In Memoriam

FRANK TANCREDE BENOIT

Dr. Frank T. Benoit, a Life Member of the Minnesota State Medical Association, died on February 7, 1955. He was seventy-three years old.

Dr. Benoit was born in Montreal, Canada. He became a naturalized citizen while still a minor through the naturalization of his father.

Dr. Benoit received his medical education at the University of Minnesota. He graduated in 1905. From 1905 until 1908, he practiced in North Dakota. He moved to Idaho and spent two years there, returning to Minnesota in 1910. He practiced for several years at Madison, Minnesota, and Slayton, Minnesota. In 1919, he settled in Winona and remained there until his death.

He was a member of the Winona County Medical Society.

WILLIAM C. CARROLL

Dr. William C. Carroll, prominent St. Paul surgeon, died March 18, 1955. He was sixty-five years old.

For many years, Dr. Carroll was associated with the St. Paul Clinic which he and Dr. Charles W. Fogarty organized in 1920. He was an attending surgeon at St. Joseph's Hospital and Miller Hospital, and a consulting surgeon at Gillette State Hospital.

Dr. Carroll was born at Lake City, Minnesota. He received his education at St. Thomas Academy and St. Thomas College in St. Paul. He received his medical training at the University of Minnesota, graduating in 1912. He interned an Ancker Hospital in St. Paul and spent two and a half years at the Mayo Clinic, for postgraduate work.

Dr. Carroll was a member of the Ramsey County Medical Society, the Minnesota State Medical Association, the American Medical Association, the Mayo Alumni Association, and the American College of Surgeons.

In 1936, Dr. Carroll was named president of the St. Thomas Alumni Association. He was elected president of the St. Paul Surgical Society in 1938.

He is survived by his wife, Lauretta; a daughter, Mrs. Margaret Clark; a son, William C., Jr., and a sister, Nellie M. Carroll, all of St. Paul.

JAMES HARRIS HAINES

Dr. James H. Haines, who had practiced medicine in Stillwater for more than fifty years, died February 16. He was eighty-three years old.

Born in Grinnell, Iowa, Dr. Haines spent his early life there and received his B.S. degree at Grinnell College. He graduated from Rush Medical college in 1895 and moved to Stillwater. He started his career as a house physician at the Stillwater Hospital, later opening an office for general practice. He was health officer of Stillwater and Washington County coroner for many years.

In 1947, Dr. Haines became a "Fifty" Club member of the Minnesota State Medical Association. He was a member of the Washington County Medical Society.

He is survived by his wife, Josephine; a daughter, Mrs. Lloyd Nelson, and two grandchildren, all of Stillwater. He is also survived by a brother, Charles, of Denver and two sisters, Mrs. F. I. Herriott of Washington and Mrs. W. G. Ray of Des Moines.

JOHN FRANCIS MADDEN

Dr. John F. Madden, fifty-three, assistant professor of dermatology and syphilology at the University of Minnesota, and director of the dermatology department at Ancker Hospital, St. Paul, died in his sleep March 9, 1955.

Dr. Madden was born in Hillsboro, Wisconsin. He received his early education at Plentywood, Montana, and came to the University of Minnesota to obtain his medical degree. After his internship at the General Hospital in Kansas City, Missouri, he spent two years at Gibbon, Minnesota. During the years 1928 to 1930, he studied at the University of Michigan. He received a degree of Master of Science in dermatology.

Dr. Madden had offices in the Lowry Medical Arts Building in St. Paul. He was a consultant at Children's and Gillette State Hospitals. He was a member of the Ramsey County Medical Society, the Minnesota State Medical Association, the American Medical Association, the American Dermatological Association, and the American Academy of Dermatology and Syphilology.

Surviving are his wife, Elizabeth; a daughter, Mary Ellen, and a son, Peter, a student at Amherst College.

ALFRED CARLTON PETERSON

Dr. Alfred C. Peterson, a veteran Minnesota physician, died March 1, 1925, at the Meeker County Memorial Hospital, Litchfield.

Dr. Peterson was born at Cokato, Minnesota, in 1875. He graduated from the University of Minnesota College of Pharmacy in 1898. He studied medicine later and received his degree in 1903. He practiced for one year in Shevlin, Minnesota, and another in Murdock. In 1905, he went to Dassel. He remained there and was active in medical practice almost until the time of his death.

Dr. Peterson was surgeon for the Great Northern Railway, Health Officer in Dassel, member of the Litchfield Hospital staff, Director of the Tri-County Medical Society (now Kandiyohi-Swift-Meeker County Medical Society), and a member of the Minnesota State Medical Association.

He was also active in community affairs, and on

AMERICAN BOARD OF OBSTETRICS AND GYNECOLOGY

The next scheduled examinations (Part II), oral and clinical, for all candidates for the American Board of Obstetrics and Gynecology will be conducted at the Edgewater Beach Hotel, Chicago, Illinois, by the entire Board from May 11 through May 20. Formal notice of the exact time of each candidate's examination will be sent him in advance of the examination dates.

AMES AWARD CONTEST FOR GASTROENTEROLOGY

The American College of Gastroenterology, in cooperation with the Ames Company, Elkhart, Indiana, announces the establishment of the Ames Award Contest for papers in gastroenterology. The contest is divided into two major classes with a first prize of $250 and a second prize of $50 in each class. One class is for fellows or residents in gastroenterology, the other for first or second-year interns. An additional prize of $100 will be given for the best paper published in the *American Journal of Gastroenterology* for which no prize has been previously awarded.

All papers submitted must represent original work in the field and must not have been previously published or presented at national meetings. The approach can be either clinical or basic science. Awards will be made at the annual meeting of the American College of Gastroenterology in Chicago in October, where the first-prize winners will present their papers in person.

All entries must be received no later than September 1 by the Research Committee, American College of Gastroenterology, 33 West 60th Street, New York 23, New York.

SCHERING AWARD COMPETITION FOR MEDICAL STUDENTS

The tenth annual Schering Award competition for medical students has opened. Its aim is to encourage medical writing and exploration of current research literature.

Titles of three subjects on which American and Canadian students are invited to submit papers this year are: Current Concepts in the Management of Osteoporosis; Prevention and Treatment of Blood Transfusion Reactions; and Recent Trends in the Clinical Use of Adrenocortical Steroids.

Both a $500 first prize and a second one of $250 will be awarded for each of the three subjects. Deadline for entry forms specifying the choice of title is July 1. Manuscripts should be mailed not later than October 1. Students may compete individually or co-operatively in teams. Information and instructions are available from the Schering Award Committee, 60 Orange Street, Bloomfield, N. J.

MINNESOTA LEAGUE FOR NURSING

"Better Patient Care for a Growing State" will be the theme for the state convention of the Minnesota League for Nursing, May 11-13, 1955. Registration for the convention, including all the meetings, will be held in the Nicollet Hotel, Minneapolis.

At the banquet to be held in the Terrace Room Thursday evening, Dr. Harold Graning, Regional Medical Director United States Public Health Service, Chicago, Illinois, will speak on "Citizen Participation for Better Health." Guests will be welcome.

Exhibits of the Upper Midwest Hospital Conference will be displayed in the Minneapolis Auditorium.

AMERICAN CONGRESS OF PHYSICAL MEDICINE AND REHABILITATION

The Midwestern Section of the American Congress of Physical Medicine and Rehabilitation will hold a meeting in Minneapolis on May 6 in the Mayo Memorial Auditorium in the Mayo Memorial Building on the University campus. Registration will be at 8:30 a.m. without charge. In addition to scientific papers, there will be a tour of the facilities of the Department of Physical Medicine and Rehabilitation in the Mayo Memorial Building. All interested physicians are invited to attend. For further information, write to the chairman, Dr. G. K. Stillwell, 200 First Street Southwest, Rochester, Minnesota.

CONTINUATION COURSES

Introduction to Electrocardiography will be the title of a continuation course for physicians which will be presented by the University of Minnesota at the Center for Continuation Study, May 9 to 14, 1955. As its name implies, this year's course is intended primarily for physicians with little or no previous experience in electrocardiographic interpretation. Basic principles, variations in normal patterns, and frequently observed abnormalities will be stressed. Registrants will have an opportunity to interpret more than 200 electrocardiograms under supervision of qualified instructors.

The University of Minnesota announces a continuation course in *Surgery for General Surgeons* which will be held at the Center for Continuation Study from May 26 to 28. Recent important advances in surgery will be discussed. Guest speaker will be Professor Ian Aird of the University of London Postgraduate Medical School. Professor Aird will also deliver the annual E. Starr Judd Lecture on May 26. The course will be presented under the direction of Dr. O. H. Wangensteen, professor and chairman, Department of Surgery.

TECHNICAL EDITORS AND WRITERS NEEDED

The United States Civil Service Commission announces that an examination is open for technical editors and writers in the fields of physical sciences and engineering, and medical sciences. The positions pay $3,410 to $10,800 a year and are located in the Potomac River Naval Command and other Federal agencies in Washington, D. C., and vicinity.

No written test is required, but applicants must have had appropriate experience or a combination of education and experience. Further information and application forms may be obtained at many post offices throughout the country, or from the U. S. Civil Service Commission, Washington 25, D. C.

TRUDEAU SCHOOL OF TUBERCULOSIS

Despite the closing of the clinical facilities of the Trudeau Sanatorium, the forty-first session of the Trudeau School of Tuberculosis will begin June 1 and continue to June 29. The staff, facilities and skills of the Trudeau organization laboratories, of the various sanatoria in the Saranac Lake area, and of the practicing tuberculosis specialists of Saranac Lake will be called upon as in the past to present the program.

The course will cover all aspects of pulmonary tuberculosis and also certain phases of other chronic chest diseases, including those of occupational origin.

Registrations will be limited and it is suggested that those planning to attend make early application for enrollment. The tuition is $100, payable to the Trudeau School on or before the opening date, June 1. A few scholarships are available for those individuals who can qualify. Applications and more detailed information may be obtained from Secretary, Trudeau School of Tuberculosis, Box 200, Trudeau, New York.

In Memoriam

(Continued from Page 282)

March 28, 1949, the residents of Dassel honored Dr. Peterson at an Appreciation Day.

Dr. Peterson is survived by his wife, Karen Marie; two daughters, Mrs. Harold R. Havig, Owatonna, and Mrs. Seymour N. Gayner, Chaska; five grandchildren; two brothers, John of Dassel and Edward of Knapp; one sister, Mrs. Oscar Sandeen of Mound.

ERNEST G. STERNER

Dr. Ernest G. Sterner, St. Paul surgeon, died January 20, 1955, after an illness of several months. He had retired from practice less than a year before. He was seventy-two.

Dr. Sterner was born at Ohr, Sweden, in 1882. He graduated from Hamline University's medical school in 1906. He had been a resident of St. Paul for sixty-four years.

President of the Ramsey County Medical Society in 1923, Dr. Sterner was also a life member of the Minnesota State Medical Association, a member of the St. Paul Surgical Society, the American Medical Association and the Phi Rho Sigma fraternity, and past chief of staff at Bethesda Hospital.

Survivors are his wife, Elizabeth; two daughters, Mrs. Edwin Frenzel, Oaklawn, Ill., and Mrs. Charles Morscheck, Lansing, Mich,; a son, Dr. John H. Sterner, St. Paul; and nine grandchildren.

Communication

Dear Editor:

I should like to enlist your aid in bringing to the attention of Minnesota doctors information about the availability of the service of the Calvert School for the education of home-bound children of elementary school age.

Calvert is an unendowed non-profit institution in Baltimore, regularly accredited by Maryland's department of education. Since 1905 it has provided an elementary school education by mail, from kindergarten through the Ninth Grade, for children who cannot attend regular schools. It pays particular attention to the problems of the home-bound child. It is not in competition with the visiting teacher programs of the public school systems; rather, it reaches areas beyond the range of those programs.

As a non-profit organization, Calvert has a primary interest in extending its service where needed rather than in increasing its enrollment.

Very truly yours,
Donald C. Thompson

30 Rockefeller Plaza,
New York 20, N. Y.

Woman's Auxiliary

HENNEPIN AUXILIARY CONVENTION HOSTESSES

Minnesota doctors' wives are cordially invited to attend the 33rd annual meeting of the Woman's Auxiliary to the Minnesota State Medical Association in Minneapolis, May 23, 24 and 25. Headquarters will be in the Hotel Radisson.

Numerous interesting events have been planned by the Woman's Auxiliary to the Hennepin County Medical Society, with Mrs. Clyde M. Cabot and Mrs. E. T. Evans as co-chairmen for the convention.

Advance registration will begin at 1:00 p.m., Sunday, May 22, at the Hotel Radisson, and will continue at 8:00 a.m., Monday and Tuesday. The Executive Board meeting and luncheon will be at the Minneapolis Club, beginning at 9:45 a.m., Monday, May 23. In the afternoon, a tea and style show will take place at Rothschild-Young Quinlan's, beginning at 2:30 p.m. A tour of a local candy manufacturer's studio has also been planned for Monday morning.

Monday evening, doctors and their wives will attend the annual Open House entertainment, scheduled for 9:00 p.m. at the Hotel Radisson. Hosts will be the Hennepin County Medical Society—excellent entertainment has been secured in honor of the 100th anniversary of the host society.

The official annual business meeting of the State Auxiliary will begin at 9:30 a.m., Tuesday, May 24, in the Junior Ballroom, Hotel Radisson. Annual reports will be heard and officers will be elected. Following this will be the annual luncheon, where a nationally recognized performer will entertain. Installation of officers, presentation of president's pin and gavel, and greetings from the new president will take place here, followed by the new president's first post-convention board meeting.

Tuesday evening, May 24, the annual banquet of the Minnesota State Medical Association will be held in the Ballroom of the Hotel Radisson.

Final activity of the meeting will be the Wednesday morning breakfast at the home of Mrs. Harvey Nelson.

The Hennepin County Medical Auxiliary has arranged a fine array of social and business events for this meeting, and auxiliary members, and non-members also, are urged to plan now to attend.

RAMSEY COUNTY REPORTS ACTIVITIES

Mrs. L. T. Simons

The Woman's Auxiliary to the Ramsey County Medical Society assisted in the Career Festival, March 8, 9 and 10 at St. Thomas College in St. Paul. The event brought thousands of high school and college students from the entire state to gain information about various careers they may wish to follow.

The Minnesota State Medical Association sponsored a booth at the festival. Members of the auxiliary who were on hand to be of assistance were: Mesdames R. R. Grau, Wallace A. Gleason, M. D. Hilker, L. F. Freidman, H. H. Fesler, C. W. Froats, A. J. Felion, Jr., Alexander McEwan, L. T. Simons. Arrangements were made by Mrs. Douglas Kusske and Mrs. W. P. Gardner, Ramsey Auxiliary president. These members, assisted by seniors from the St. Thomas pre-medical school, gave out information and literature to students interested in a medical career.

Mrs. W. P. Gardner, president, called a board meeting on March 21 in the Medical Arts Library. During and following the meeting, cancer dressings were made.

Mrs. D. R. Gillespie, chairman for *Today's Health* subscriptions, and Mrs. Frank Milnar had charge of a booth on March 28 during the "What's Cooking?" program. Pamphlets and posters were on display, and magazines were sold by the copy and by subscription.

Our case work representative, Mrs. Alexander McEwan, attends a monthly meeting at which welfare groups are represented. Bills in the legislature and civic problems are explained and discussed.

Mrs. Wallace Gleason, press chairman, and Mrs. John Madden attended a meeting of the Historical Society on February 17. Dome Club members were guests of the society at a tea and lecture by Nobel prize winner, Dr. Philip Hench, of Rochester.

The auxiliary sent contributions to the Crusade for Freedom and also to the Civic Opera Association, the latter to be used to purchase tickets for the blind to attend the opera's presentation of "Oklahoma."

COUNTY AUXILIARIES REPORT HEALTH PROJECTS

Mrs. L. Raymond Scherer

Following a request to the presidents of the county auxiliaries, several have reported on some of their community activities in the health field.

The most popular is in the field of nurse recruitment—entertaining and informing the high school students of the possibilities of a career in that profession.

Wright, Redwood-Renville and McLeod Auxiliaries helped in the poliomyelitis, heart and cancer fund-raising campaigns. Wright and Hennepin Auxiliaries also made cancer dressings, as did Ramsey Auxiliary. Redwood-Renville Auxiliary also helped with the Red Cross Mobile Unit, Wabasha Auxiliary worked with a local PTA and arranged to bring Dr. Roy C. Burt of the Anoka State Hospital to speak for their March meeting.

Hennepin County Auxiliary gives financial support to many health and health education organizations.

St. Louis County Auxiliary arranged a most interesting meeting honoring Dr. Kate P. Newcomb, a physician from Woodruff, Wisconsin. She had been the "star" on "This Is Your Life." A result of that program was a fund of $110,000 to complete and furnish the Lakeland Memorial Hospital in Woodruff. In Duluth, 200 were present to hear her and to see the film of the national television network program on her life.

Of General Interest

Dr. E. M. Hammes, St. Paul, attended the regional research meeting of the American Psychiatric Association in Galveston, Texas, on February 18 and 19. The entire meeting, he reported, was devoted to the physiologic basis, values, limitations and hazards of pharmacologic products recently introduced in the treatment of psychiatric disorders. Dr. Hammes drove to the meeting from Florida, where he had spent his winter vacation.

* * *

Dr. Cyril M. Smith, Duluth, St. Louis County coroner, was principal speaker at a meeting of the Duluth Association of Accident and Health Underwriters in mid-February. Dr. Smith discussed cardiovascular diseases and occupational and industrial hazards.

* * *

"Self-Medication" was the title of a radio talk given by **Dr. Donald M. Odland,** Luverne, over station KWOA, Worthington, on February 20. He discussed the dangers invited by persons who diagnose and prescribe for themselves. His talk was presented on "Your Health Hour," a program sponsored by the Southwestern Minnesota Medical Society and Auxiliary and the Minnesota Department of Health.

* * *

Dr. Irving C. Bernstein, Minneapolis, has been elected to membership in the American Psychosomatic Society.

* * *

Dr. Edward H. Juers, Red Wing, attended a one-week meeting of the American Academy of Orthopedic Surgery in Los Angeles early in February.

* * *

Dr. Charles H. McKenzie, Minneapolis, has announced that **Dr. Francis M. Swain** is now associated with him in the practice of gynecology and obstetrics, with offices at 1035 Medical Arts Building, Minneapolis.

* * *

Among physicians who attended the tenth National Rural Health Conference in Milwaukee in late February was **Dr. Paul C. Leck** of Austin.

* * *

Dr. Frederic F. Wipperman, Minneapolis, was recently elected president of the Edina Optimist Club, a civic-minded organization whose motto is "Friend of the Boy." Dr. Wipperman has practiced ophthalmology in Minneapolis since 1946.

* * *

Dr. O. M. Heiberg, Worthington, presented a special lecture for senior medical students at the University of Minnesota late in February. As part of a course in "Orientation to Practice," he discussed the subject of practicing in a clinic.

Dr. Jack V. Wallinga, formerly of Minneapolis, recently attended the American Orthopsychiatric Association meeting in Chicago. Dr. Wallinga is now stationed at the U. S. Naval Hospital, Oakland, Calif., where he is clinical director of the neuropsychiatric service.

* * *

Dr. Berry Campbell, associate professor of anatomy at the University of Minnesota, presented a series of lectures on the nervous system at medical centers in Norway, Sweden and The Netherlands in March. He returned to Minneapolis on March 25. Sponsor of his lecture tour was the University of Leiden.

* * *

Guest speaker at a meeting of the Women's Auxiliary of Immanuel Hospital in Mankato in mid-February was **Dr. H. J. Nilson** of Mankato. He spoke on the hospital and medical situation in Sweden, where he visited last year.

* * *

Dr. C. J. Watson, head of the department of medicine at the University of Minnesota Medical School, is visiting the Middle East during April to lecture and conduct conferences in medical schools in Lebanon, Iraq, Syria, Jordan, Egypt and Israel. His trip is sponsored by the International Education Division of the U. S. Department of State. He will return to Minneapolis on May 3.

* * *

Dr. James A. Leigh has been appointed city health officer in East Grand Forks. He succeeds the late Dr. G. P. Kirk, who died January 20 after holding the office for more than thirty years. Dr. Leigh has practiced in East Grand Forks since 1953.

* * *

The American College of Surgeons has awarded a $20,000 research grant to **Dr. Fletcher A. Miller,** a surgery research fellow at the University of Minnesota Medical School. The grant will cover a three-year period beginning July 1, 1955. Through his research thus far at Minnesota Dr. Miller has developed the use of a mass spectrometer to determine the level of carbon dioxide developed by a patient during surgery.

* * *

Dr. Andrew Sinamark, Hibbing, was the principal speaker at a meeting of the Kiwanis Club at Ely late in February. He showed pictures of a trip he made last summer to the Pacific islands.

* * *

A new surgical textbook, "Surgery of the Small and Large Intestine," by **Dr. C. W. Mayo,** Rochester, has just been published by the Year Book Publishers, Inc., of Chicago. The book, consisting of 340 pages and 94 plates, was illustrated by Russell Drake of the art studio of the Mayo Clinic.

Dr. Milton Howell, Glencoe, was the principal speaker at a meeting of the Glencoe Business and Professional Women's Club in late February. Dr. Howell discussed "Cancer in Women and Manner of Self-detection." A motion picture on the same subject preceded his talk.

* * *

During the middle of March, **Dr. A. C. Hilding**, Duluth, was in Hollywood-by-the-Sea, Florida, attending meetings of the American Laryngological Association, the American Triological Society and the American Otological Society. He was elected to membership in the American Otological Society on March 17. On April 6 and 7, Dr. Hilding presented a series of four lectures on eye and ear research at the annual Spring Congress in Ophthalmology and Otolaryngology of the Gill Memorial Eye, Ear and Throat Hospital, Roanoke, Virginia.

* * *

Dr. Tague C. Chisholm, Minneapolis, discussed accidents in childhood when he spoke at a meeting of the Duluth Principals and Supervisors Association and the Duluth Parent-Teachers Association Council in February.

* * *

Principal speaker at a clinical pathological conference at the Falls Memorial Hospital, International Falls, in late February was **Dr. H. E. Law**, Virginia. He discussed cancer of the stomach. The conference is held each month, featuring a specialist in some field of medicine as guest speaker.

* * *

Dr. Leo Furr, Bird Island, reported for a two-year tour of duty with the Air Force on March 11. He was associated in practice in Bird Island with **Dr. H. P. Hinderaker.**

* * *

Dr. E. S. Boone, Luverne, was the principal speaker at a meeting of the Rock County 4-H leaders at Luverne in late February.

* * *

Dr. R. N. Barr, deputy state health commissioner, discussed "How Safe Is Your Child" at a meeting of the women's section of the Industrial Safety School in Duluth on March 9.

* * *

Among physicians attending the eighteenth annual meeting of the New Orleans Graduate Medical Assembly in New Orleans, March 7 to 10, was **Dr. R. R. Wright** of Austin.

* * *

Dr. and Mrs. J. A. Myers, Minneapolis, spent a week in mid-March on a business and pleasure trip to Puerto Rico. During the trip Dr. Myers, who is professor of preventive medicine at the University of Minnesota, gave a series of lectures at San Juan, Puerto Rico.

* * *

While returning from a medical meeting in Chicago in mid-February, **Dr. John B. Frost**, Minneapolis, suffered minor injuries when a train on which he was riding was derailed near Waukegan, Illinois.

Dr. John B. Moyer, Duluth, has been appointed president of the Duluth Heart Council, a group which aims at disseminating programs of public and professional education.

* * *

Dr. Robert Gray, formerly of Marshall, was married to Betty Batcup of Devon, England, on January 29. The wedding took place in Nairobi, Kenya, Africa. Dr. Gray left for Africa on a Ford Foundation fellowship in August, 1954. He has completed research in health, hospital and medical practices in Kenya and will continue his research for eighteen months in Tanganyika and Uganda. Dr. Gray is the son of **Dr. and Mrs. F. D. Gray** of Marshall.

* * *

A scientific motion picture produced at the University of Minnesota has received a second-place silver medallion from the Screen Producers Guild in Los Angeles. The film, "One Victory," is a presentation of a low-temperature heart operation performed by **Dr. Richard Varco, Dr. F. John Lewis** and **Dr. Mansur Taufic.**

* * *

Dr. W. F. Mercil, Crookston, was the principal speaker at a meeting of the Mathein Club in Crookston on March 7. He spoke on the topic, "Preventive Medicine in the Human Female."

* * *

Dr. John M. Waugh, Rochester, was one of the speakers at a sectional meeting of the American College of Surgeons in Nashville, Tennessee, on April 4. He discussed "Various Types of Gastrectomy."

* * *

Maj. Gen. Silas B. Hays, a native of St. Paul, has been nominated by President Eisenhower to be Surgeon General of the Army, effective June 1. Dr. Hays, who has been deputy surgeon general for the past four years, would succeed Maj. Gen. George E. Armstrong, who is scheduled to retire.

* * *

Dr. David Allison, Litchfield, left on March 14 to begin a two-year tour of duty in the Air Force. While he is on military duty, his practice will be handled by his associate, **Dr. Gregory Olson** of Litchfield.

* * *

At the age of ninety-two, **Dr. Fletcher W. Penhall**, Willmar, retired from active practice on March 1. Dr. Penhall, a graduate of Bellevue Medical Center in New York, began practicing in Morton in 1891. After fifty-three years of practice there, he moved to Willmar and became a member of the staff of the Willmar State Hospital in 1944. Now in retirement, Dr. Penhall is again living in Morton.

* * *

A testimonial dinner honoring **Dr. E. E. Novak** of New Prague was held in Jordan by King Hiram Lodge, A.F. and A.M., on February 22. At the dinner, residents of the area paid tribute to Dr. Novak for his almost sixty years of service as a physician in New Prague. Representatives of numerous fraternal organizations were on hand to honor him and to present him with a watch to mark the occasion. Dr. Novak was graduated from the University of Iowa in 1895. He served as a member of the University of Minnesota Board of Regents for twenty-two years.

* * *

In Hallock three physicians have combined to form the Hallock Clinic. They are **Dr. J. E. Nord, Dr. Anthony S. Berlin** and **Dr. P. J. Parker**. The clinic will be housed in the building formerly occupied by Dr. Nord. The building has been completely remodeled and redecorated to provide proper quarters for the new medical center.

* * *

The Minnesota State Medical Association's new television series, "Doctor's Digest" appears weekly over KEYD-TV. The show, jointly sponsored by the Association and the University of Minnesota, can be viewed from 6:30 to 7:00 p.m. on Thursday evenings. **Dr. James Rogers Fox**, Minneapolis, serves as moderator and the show features regular medical tips of the week and medical news of the week, plus panels, interviews and film clips. Billed as a "medical variety show," it is hoped that "Doctor's Digest" will bring important medical and health news to the people of the state.

* * *

The alumni of the Cyrus Fishermen's College will hold its 17th annual banquet at Cyrus, Minnesota, April 29, at 7 P.M. **Dr. H. Linde**, who has practiced medicine in Cyrus nearly fifty years, is president of the college. All Minnesota doctors are cordially invited to this banquet of walleye pike.

NEW LOCATIONS

Dr. Ralph Rayner, formerly of Gibbon, has become associated in practice with **Dr. David F. Struxness at Glencoe**. A graduate of the University of Minnesota Medical School, Dr. Rayner interned at Minneapolis General Hospital. He practiced at Gibbon for the past three years.

Dr. Arthur Neumaier has returned to Glencoe to resume the practice of medicine there following a period of study at the Veterans Administration Hospital in Minneapolis.

Dr. Charles T. Louisell, who recently was released from active duty with the Navy, has opened offices for the practice of medicine in Fairmont. A graduate of the University of Minnesota in 1944, he specialized in ophthalmology and otolaryngology before beginning his military service.

Dr. John B. Maunder, who recently completed two years of duty in the Air Force, has become associated with the Oxboro Clinic in Richfield. A graduate of the University of Minnesota in 1945, he specialized in obstetrics and gynecology before entering the Air Force.

Dr. D. W. Sontag, formerly of Long Beach, Calif., has become associated in practice with **Dr. E. C. Bayley** and **Dr. B. A. Flesche** in Lake City. He is a graduate of the University of Minnesota.

HOSPITAL NEWS

The results of elections conducted recently by the medical staffs of numerous Minnesota hospitals have been announced. Among the election results reported are the following:

Fairview Hospital, Minneapolis: Dr. Glenn Petersen, chief of staff; Dr. L. J. Roberts, chief-elect; Dr. Lester W. Carlander, Jr., treasurer; Dr. Stanley Stone, secretary.

Montevideo Hospital, Montevideo: Dr. L. A. Krystosek, chief of staff; Dr. J. H. Allen, vice president; Dr. E. G. Hustad, secretary-treasurer.

Municipal Hospital, Worthington: Dr. C. R. Stanley, chairman; Dr. D. J. Halpern, vice chairman; Dr. Raymond Minge, secretary.

St. Joseph's Hospital, Brainerd: Dr. R. L. Cushing, chief of staff; Dr. E. R. Kanne, vice chief of staff; Dr. Maurice Meller, secretary-treasurer.

Doctors Memorial Hospital, Minneapolis: Dr. Allan J. Blake, chief of staff; Dr. Richard H. Beiswanger, assistant chief of staff; Dr. Fred A. Rice, secretary.

Miller Memorial Hospital, Duluth: Dr. F. T. Becker, chief of staff; Dr. John F. Schmid, vice chief of staff; Dr. John J. Dwyer, secretary-treasurer.

St. Francis Hospital, Shakopee: Dr. I. B. Heinz, chief of staff; Dr. B. F. Pearson, assistant chief of staff; Dr. Harry Simmonds, secretary-treasurer.

St. Barnabas Hospital, Minneapolis: Dr. Arthur H. Mork, chief of staff; Dr. Lloyd F. Sherman, vice chief of staff; Dr. John T. Moehn, secretary-treasurer.

St. Gabriel's Hospital, Little Falls: Dr. A. H. Benson, president; Dr. David Hoehn, vice president; Dr. G. W. Heine, secretary-treasurer.

St. Luke's Hospital, Duluth: Dr. M. F. Fellows, chief of staff; Dr. Arden L. Abraham, chief-elect; Dr. H. J. Jeronimus, secretary.

Community Hospital, Fairmont: Dr. O. E. Wandke, president; Dr. A. L. Ourada, vice president; Dr. H. A. Williamson, secretary.

Asbury Hospital, Minneapolis: Dr. Wayne S. Hagen, chief of staff; Dr. Einar Monson, vice president; Dr. M. Elizabeth Craig, secretary-treasurer.

Olmsted Community Hospital, Rochester: Dr. Theodore O. Wellner, president; Dr. James R. Doyle, vice president; Dr. R. L. Page, secretary.

St. Mary's Hospital, Minneapolis: Dr. James E. Trow, chief of staff; Dr. C. N. Borman, vice chief of staff; Dr. John Kelly, secretary-treasurer.

Community Memorial Hospital, Faribault: Dr. Ernest J. Nelson, chief of staff; Dr. Paul Stahler, vice chief of staff; Dr. Elizabeth Reischl, secretary-treasurer.

St. Joseph's Hospital, Saint Paul: Dr. J. P. Medelman, president; Dr. Bernard O'Reilley, vice president; Dr. Francis W. Lynch, secretary; Dr. C. L. Cain, treasurer.

City Hospital, Owatonna: Dr. O. W. Roberts, president; Dr. Frank C. Anderson, vice president; Dr. K. G. Henry, secretary-treasurer.

Glenwood Hills Hospital, Minneapolis: Dr. Irving Bernstein, chief of staff; Dr. John Schumacher, vice president; Dr. Jennings Peteler, secretary-treasurer.

St. Mary's Hospital, Duluth: Dr. Karl E. Johnson, chief of staff; Dr. R. E. Nutting, chief-elect; Dr. J. C. O'Neill, secretary.

MINNESOTA BLUE SHIELD - BLUE CROSS

Blue Cross

During the month of January, 1955, 11,119 participant subscribers were enrolled in Blue Cross bringing the net enrollment as of January 31, 1955, to 1,002,760 participant subscribers.

Hospitalization expense incurred by Blue Cross subscribers during the month of January, 1955, amounted to $1,374,711.70.

Effective March 1, 1955, a Washington, D. C., office of the Blue Cross Commission will open the Artemas C. Leslie, Associate Director of the Blue Cross Commission in charge.

The reasoning for opening of the Washington office was due to the importance and frequency of contracts with our Federal Government which assures full time staff attention to Washington affairs.

Artemas C. Leslie is a Pittburgh attorney and for the past five years has been Insurance Commissioner of Pennsylvania. He was originally appointed in 1950 by Governor James H. Duff and reappointed by Governor John S. Fine. Under Leslie, many new fields of insurance activity were opened up, including new concepts of multiple-line underwriting, "package" policies, and other experimentations.

Leslie has been active in the affairs of the National Association of Insurance Commissioners. He has been a member of the Association's Executive Underwriting Powers as well as chairman of the Subcommittee on Blue Cross and Blue Shield of the Accident and Health Committee.

Leslie is senior partner in the law firm of McCloskey, Best & Leslie, of Pittsburgh. He is a member of the Allegheny Counuty, Pennsylvania, and American Bar Associations, the National Insurance Bar, the Federation of Insurance Counsel, American Law Institute, and American Judicature Society. He is admitted to practice in the State and Federal Courts, including the Supreme Court of the United States.

Blue Shield

Of increasing interest are the Blue Shield statistical data compiled annually which show the number of different types of services furnished Blue Shield subscribers by doctors of medicine. On a comparative basis, each type of service in 1954 increased numerically over the number of such services in 1953, and the average payment for each type of service also showed an increase. Such services as in-hospital medical care, emergency medical care, obstetrical, surgical and ancillary services showed a marked increase both in the number of cases in 1954 as compared with 1953, and in the amount paid by Blue Shield for such services.

During 1953, the average payment made to doctors for in-hospital medical care was $24.66 per claim. In the year 1954, this average increased to 29.01 per service and the number of such services increased 15% over 1953. More remarkable is the increase in emergency medical care payments and the increase in the number of such claims compared with the year 1953. Payments in 1953 for emergency medical care averaged $338.48 per claim. In the year 1954, this average payment increased to $43.02 per claim, or an increase of $4.54 more than the average amount paid per claim in 1953. In addition, the number of claims of this nature in 1954 almost doubled the number paid in 1953.

Obstetrical services furnished Blue Shield subscribers have always been one of the most frequent Blue Shield services. During 1953, the average cost per claim for this service was $52.52. During the year 1954, the average cost per service was $60.20. It is also noted that an increase of 698 in the total number of obstetrical services was experienced in 1954 as compared with 1953.

In reviewing the data on surgical services rendered to Blue Shield subscribers, an increase of 16 per cent was experienced in the total number of surgical services provided during 1954. Other types of services showing marked increases are those known as ancillary services. These include anesthesia, x-rays and endoscopic services. For each type of ancillary service during the year 1954 substantially more benefits were paid by Blue Shield for services rendered to subscribers.

It is apparent from these analyses that in both the number of services and the amounts paid for the different services, Blue Shield payments to doctors have grown appreciably in 1954 as compared with 1953. There is great likelihood that payments both in number and costs will be even greater in 1955.

MINNESOTA ACADEMY OF MEDICINE

(Continued from Page 275)

met. Some of these ideas and ideals have been mentioned by some of our distinguished former presidents and I simply wish to implement their fulfillment. Each of you will have time to evaluate them and I beg your indulgence to give these matters your early consideration in the coming year.

Dr. Regnier, of Minneapolis, read his address as retiring president on "Hormonal Treatment of Metastatic Carcinoma of the Breast." Lantern slides were shown.

The meeting adjourned.

Robert E. Priest, M.D., *Secretary*

BOOK REVIEWS

Books listed here become the property of the Ramsey, Hennepin and St. Louis County Medical Libraries when reviewed. Members, however, are urged to write reviews of any or every recent book which may be of interest to physicians.

EARLY CARE OF ACUTE SOFT TISSUE INJURIES. Committee on Trauma, American College of Surgeons. 192 pages. Price $1.00, paper cover. Chicago: American College of Surgeons, 1954.

AN OUTLINE OF THE TREATMENT OF FRACTURES. Fifth Edition. Committee on Trauma, American College of Surgeons. 93 pages. Illus. Price $1.00, paper cover. Chicago: American College of Surgeons, 1954.

ION EXCHANGE AND ADSORPTION AGENTS IN MEDICINE. Gustav J. Martin, Sc.D., Research Director, National Drug Company, Philadelphia. 333 pages. Illus. Price $7.50, cloth. Boston: Little, Brown & Co., 1955.

SURGERY OF THE SMALL AND LARGE INTESTINE. Charles W. Mayo, M.D., Section of Surgery, Mayo Clinic, Rochester, Minnesota; Professor of Surgery, Mayo Foundation, Graduate School, University of Minnesota. 340 pages. Illus. Price $9.00, cloth. Chicago: Year Book Publishers, Inc., 1955.

THE MEDICAL CARE OF THE AGED AND CHRONICALLY ILL. Freddy Homburger, M.D., Research Professor of Medicine, Tufts College Medical School. 253 pages. Illus. Price $5.75, cloth. Boston: Little, Brown & Co., 1955.

NATIONAL PLUMBING CODE. Sponsored by American Public Health Association and American Society of Mechanical Engineers. 174 pages. Price $3.50, paper. New York: American Society of Mechanical Engineers, 1955.

THE HEALTH VISITOR AND TUBERCULOSIS. By Sheena H. Buchanan, SRN, SCM, HV Cert, Assistant Superintendent Nursing Officer in Charge of Health Visitors, Northamptonshire County Council. Foreword by J. Greenwood Wilson, M.D., FRCP, DPH, Medical Officer of Health, Port of London, Formerly Medical Officer of Health, City & Port of Cardiff. Preface by G. B. Lord, M.D., Physician Superintendent, Rushden House Sanatorium, Northamptonshire. 150 pages, including facsimiles of report cards. Clothbound. Price 8s. 6d. London: The National Association for the Prevention of Tuberculosis, 1955.

Here, in concise and readable form, is a practical guide for health visitors in tuberculosis written from the author's own experience. Although she treats in detail the minute-to-minute practicalities of routine work and considers such wide questions as general and specialized health visiting, the health visitor and the chest clinic, and the changes brought about by the National Health Service Act, Miss Buchanan never forgets the human aspect. The family is the central social unit and courage and patience are the prime attributes of the good health visitor trying to help them. No one in the public health work should miss this latest contribution to the welfare of the tuberculous.

ANATOMY; REGIONAL AND APPLIED. By Raymond Jack Last, M.B., B.S. (Adel.), F.R.C.S., Professor of Applied Anatomy, Royal College of Surgeons of England. 665 pages. Illus. Price $10.00. Boston: Little, Brown and Company, 1954.

This book on human anatomy is written to help the reader understand anatomy. It is in no sense a book on surgical anatomy, in which the reader is given a short course in surgical technique rather than anatomy. The book is divided on a regional basis. The embryological and functional aspects are given. An added feature is the bibliographical notes at the end of the book. An adequate index is given and the book is well printed. It should enjoy a wide popularity.

C. E. Rea, M.D.

BOUND COPY OF BULLETIN ON RHEUMATIC DISEASES AVAILABLE

The first four volumes of *The Bulletin on Rheumatic Diseases* have been bound in soft cover and are now available to physicians.

The Bulletin, published by the Arthritis and Rheumatism Foundation, is issued nine times a year and is available without charge to all physicians and medical students who request it.

Physicians wishing to regularly receive *The Bulletin on Rheumatic Diseases* at no cost, should write to Dr. Russell L. Cecil, Medical Director, Arthritis and Rheumatism Foundation, 23 West 45th Street, New York 36, N. Y.

The bound special volume composed of all issues of *The Bulletin* of the past four years, is available from the Arthritis Foundation at the cost of $1.

The Bulletin, the only American publication in the field of the rheumatic diseases, was started in 1950 to foster greater interest in the rheumatic diseases among physicians. Its aim is to keep doctors abreast of the more important clinical advances and changing concepts of the rheumatic diseases promptly, simply and succinctly.

The Bulletin at present is being distributed to 22,500 physicians throughout the United States and tweny-five foreign countries.

"PRESCRIPTION FOR MEDICAL PARTNERSHIPS"

"Prescription for Medical Partnerships," a general information booklet on the business details of establishing and continuing a group medical practice, has been prepared by Dr. Charles Maertz, retired Medical Director of the Union Central Life Insurance Company.

A copy can be obtained by writing to "Medical Partnerships," Field Service Division, P.O. Box 179, Cincinnati 1, Ohio.

General Practice Symposium

Neurodermatitis

LOUIS A. BRUNSTING, M.D.
Rochester, Minnesota

THE commonest disease of the skin is eczema, and the commonest form of eczema is neurodermatitis, which is merely a word to express the relationship between the nervous system and the skin. Various forms of neurodermatitis occur, such as the exudative form characterized by blisters on the fingers or oozing widespread plaques, which may occur in childhood as well as in older persons. The commonest form, however, is the circumscribed thickened plaque called "lichen simplex chronicus." These plaques, single or multiple, may occur in various places or they may become a diffuse process to the extent of exfoliative dermatitis. The patient may be entirely incapacitated and be miserable day and night because of the outstanding symptom of itching, often paroxysmal in nature; many patients are driven to distraction and almost to suicide.

Lichen simplex chronicus occurs in certain types of persons who may have hay fever, asthma or urticarial tendencies. Thickening of the skin results from scratching. This thickening brings on exudation and nonspecific cellular reaction; the tissues are thus changed so that itching results and a vicious cycle is established.

The most familiar site for the appearance of lichen simplex chronicus is along the lateral surface of the thighs, on the shins, about the ankles and on the elbows or knees, where the lesions resemble those of psoriasis. A peculiar form occurs in the nuchal region of women almost exclusively, as well as behind and in the ears; an extremely common form of neurodermatitis, or lichen simplex chronicus, produces the symptoms of pruritus vulvae or ani.

The presence of neurodermatitis around the ankle always brings up the question of whether or not varices are present. One must distinguish neurodermatitis of the lower portion of the legs from so-called stasis dermatitis. Whenever any disturbance occurs in the lower part of the legs, hydraulic factors come into play, and any time the skin is injured, the circulation becomes stagnant in that region. It is rare to relieve these patients of their symptoms by treatment of varicose veins, although the use of an ace bandage is helpful for two reasons, namely swelling is prevented and the site is covered so that scratching is not possible.

When the disease reaches the proportions of exfoliative neurodermatitis, it is extremely difficult to arrive at a satisfactory diagnosis. The contiguous lymph nodes are invariably enlarged and present an almost irresistible demand for biopsy. Other diagnostic facilities should be utilized first, for in such patients the site from which the specimen has been removed for biopsy frequently becomes infected. The microscopic picture of the nodes is usually one of reticulum cell hyperplasia, plus the presence of pigment and fat. Pathologic diagnoses such as lipomelanoreticuloendotheliosis may be returned, although the condition is nothing but a scavenger reaction in the lymph nodes as the result of extensive chronic dermatitis. Biopsy of the skin shows a rather nonspecific picture that may be almost impossible to distinguish from that of psoriasis. A patient who has dermatitis of this magnitude is entirely incapacitated. As already indicated, some patients who have this syndrome have had asthma, eczema, hay fever and urticaria off and on since infancy.

Read at the meeting of the Minnesota Academy of General Practice, Rochester, Minnesota, October 20, 1954.

From the Section of Dermatology, Mayo Clinic and Mayo Foundation.

The Mayo Foundation, Rochester, Minnesota, is a part of the Graduate School of the University of Minnesota.

In not a few of them, opacities in the lenses will develop that are typical of allergic cataracts. Therefore, one test in these patients should be routine screening by slit-lamp examination to detect such changes in early stages. If such lesions are found, serious restrictions are placed on the patient's activities.

The localized plaque of neurodermatitis may be treated by topical measures. Protective pads, such as an elastoplast cutout, placed over the plaque are sometimes helpful. Tying the hands at night is of aid in some of these conditions, as is any artificial device to break the cycle of the scratching reflex. Systemic measures, such as allergic surveys and dietary restrictions to remove supposedly allergenic foods, are practically worthless. A mistake is often made in prescribing ointments containing a local anesthetic agent, such as dibucaine hydrochloride (nupercaine) or benzocaine, for the relief of itching. Sooner or later, sensitivity to these agents develops and the original condition becomes aggravated and widespread. The same is true in the presence of slight infection, when the prescribing of sensitives, such as nitrofurazone (furacin) is to be condemned. The use of roentgen therapy in moderate doses is helpful; however, excessive amounts of such treatment produce actinodermatitis, which leads to no end of complications.

Dietary control is prescribed for patients who have gained weight; patients who have hypertension should have proper restrictions from the standpoint of their general health. Sometimes in women this condition first appears during the menopausal years; under these conditions, some estrogenic support is helpful. When neurodermatitis becomes widespread and the patient is extremely unstable, some restrictions should be made on the excessive activity. These people usually are hyperactive and like to improve every shining minute. The typical woman who has neurodermatitis never sweeps anything under the rug. She may be on a committee; soon she is chairwoman and soon there are no other members on the committee but this woman—she's the chairwoman and the entire committee. It is useless to attempt to find an ointment in this jar or that to correct the symptoms which are trying to tell us that such a patient is about to blow a fuse. Phenobarbital is helpful but it is also sometimes capable of provoking allergic reactions. Some favorable results have been attained by use of reserpine (serpasil), even in the absence of hypertension, because of the tranquilizing effect of this agent. Chloral hydrate is a useful bedtime sedative.

Topical applications in the acute stage include use of moist compresses of boric acid (saturated solution) or aluminum subacetate. The latter is prescribed as an 8 per cent solution that is to be diluted 1 fluidounce to a pint. It is not used as a wet poultice but as a moist dressing; it is useful in relieving the irritation.

One of the most successful but rather messy treatments is the use of tar. It can be prescribed as an ointment containing 1 or 2 per cent each of crude coal tar and salicylic acid. If tar is used in the hair, it should be incorporated in a water-soluble base.

Dermatitis of the ear canal is often neurodermatitis, and fungi are not involved. It is necessary to clean out the canal frequently. A small wick of moist dressing may be helpful. The most characteristic reaction in this location is intense itching, and the patient perpetuates the condition by scratching. In the treatment of ear conditions, nuchal eczemas and pruritus vulvae et ani, use of an ointment containing 1 per cent hydrocortisone is helpful. The effect of this steroid applied locally wears out in time unless the underlying disturbances are corrected, but it has been a most significant advance in treatment. I have no brief for those who would use cortisone or corticotropin (ACTH) systemically for the treatment of neurodermatitis, even when the condition becomes generalized, because the patient becomes dependent on it and it is difficult to discontinue treatment without a rebound reaction. Occasionally, when the condition is uncontrollable, it is useful to give 15 to 25 mg. of ACTH intravenously as an eight-hour drip in a 5 per cent solution of glucose.

As already emphasized, patients who have widespread neurodermatitis are incapacitated and really need hospitalization for immediate relief. In long-range treatment they need readjustment of their habits of living and sometimes a change of environment. Some of the mañana influence of the Southwest is helpful and the sunlight there is also beneficial.

Differential Diagnosis of Tumors of the Neck

OLIVER H. BEAHRS, M.D.
Rochester, Minnesota

ANY tumor of the neck, as is one in any other place in the body, is potentially dangerous and should be treated accordingly. The only way to establish a definite diagnosis is by histologic study, which requires biopsy or removal of the lesion. The best time to carry out primary treatment of a tumor in the neck, especially if it is malignant, is at the time of biopsy. Therefore, it is important to use every possible means to establish a preoperative working diagnosis so that the physician can better explain to the patient and his relatives what might be expected in the way of definitive treatment.

It is for these reasons that one always should keep in mind the differential diagnosis of tumors in the neck when a patient is being examined. For instance, if a lesion should prove to be a squamous cell epithelioma metastatic from a primary tumor in the mouth, there is no better time to do the necessary radical dissection of the neck than when the primary lesion is removed. If one strongly suspects that a lesion is squamous cell epithelioma, possibly primary dissection of the neck should be done in preference to biopsy, because biopsy in squamous cell epithelioma may increase the chance of recurrence because of "seeding" at the operative site or persistence of the carcinoma because of incomplete removal of the tumor. Thus in the course of examination of the neck, one should always inspect the lip, the endoral cavity and the larynx, because of the potential danger of metastatic involvement of lymph nodes in the neck arising from primary carcinoma in these regions.

General Aspects of Examination

The examiner must consider a tumor of the neck from the standpoint of the history and the results of inspection, palpation and auscultation of the tumor. If the tumor has been present for many years without any evidence of recent change, that means one thing to the examiner; if the tumor has been present for ten or twenty years and in the past month has shown a sudden increase in size, that means something else; if the tumor was first noted a month ago and is painful and tender, that means yet another thing. One should also note whether or not there has been any difficulty in swallowing, or any recent evidence of hoarseness. One factor that is sometimes misleading is whether or not the tumor varies in size. The patient may say that the lesion increases and decreases in size. It is difficult to judge this because with change of the position of the neck, as in moving the head from side to side, the appearance of the tumor will change; it appears best to ignore this particular symptom.

For inspection, it is helpful to have the patient stand directly in front of the examiner, perhaps 2 or 3 feet away. This establishes whether or not asymmetry of the neck is present; if it is, the tumor is obvious and merely from inspection one should get some idea of its nature. Motion of the tumor up and down as the patient swallows gives certain information, perhaps indicating a nodular goiter. A tumor that is not easily apparent on inspection sometimes becomes prominent when the patient swallows. Also, movement of the head from side to side occasionally makes the tumor more prominent. Any dimpling or attachment of the skin over the tumor should be noted.

Palpation should not be attempted until after thorough inspection. The physician should feel the neck rather carefully, as some people are rather sensitive to such palpation. The tumor preferably should be grasped between the thumb and the fingers. Occasionally, however, one is unable to feel the tumor between the fingers and then it must be palpated against the deeper structures of the neck. At times, one can depress the structures of the neck with the opposite thumb, causing the tumor to become more prominent and more palpable. One should note whether the

tumor is firm or soft, encapsulated or infiltrative, solid or cystic, tender or nontender, fixed to surrounding tissues or freely movable, in which direction it moves and, if possible, from which structures of the neck it arises. When the lesion is in the upper cervical region, especially the submaxillary triangle, bimanual palpation with the fingers in the mouth is of value. One should also determine the degree of hardness or firmness. A tumor that is calcified is like a rock and usually is benign, in contrast to a firm tumor that feels as though it is infiltrating adjacent tissue; the latter type of tumor frequently is malignant. One should feel for attachment to surrounding tissues.

In the course of palpation, one should notice if there is any pulsation of the tumor. Occasionally, an aneurysm or a vascular tumor might arise from structures in the neck. It is extremely important to know this before exploration of a tumor. Auscultation of the lesion may aid in this diagnosis.

Regardless of how expert the examiner is and how certain he may be that a lesion is of this type or that, the only way to prove the point is to excise the lesion for histologic diagnosis. Then the lesion can be forgotten or the indicated definitive treatment can be carried out.

Tumors of the neck may be divided into congenital lesions, primary tumors, metastatic tumors, tumors of the salivary glands and inflammatory lesions. This presentation is primarily concerned with the characteristics of these lesions that might be of diagnostic value.

Congenital Lesions

Among congenital lesions occurring in the midline of the neck are cysts of the thyroglossal duct. This tumor occurs in the midline and lies either over or below the hyoid bone. If it is much below, the cystic mass may move slightly to the right or the left of the midline. Most often this lesion is definitely cystic; however, if it is tense it is somewhat difficult to establish its cystic nature. If one grasps the tumor and creates pressure on it downward and then feels above the tumor, between the tumor and the hyoid bone, one frequently can feel the cordlike structure that represents the tract from the cyst through the hyoid bone to the base of the tongue; palpation of such a tract renders it fairly certain that the tumor is a cyst of the thyroglossal duct. If the lesion has been previously incised, or if it has previously drained, the character of the discharge is important. A discharge from a cyst of the thyroglossal duct is mucoid in type. A cyst of the thyroglossal duct may not have been noticed in childhood and may be initially discovered in patients sixty or seventy years of age.

Among the lesions in the lateral aspect of the neck are branchial cleft cysts, which occur in the submaxillary triangle, usually just anterior to the anterior border of the sternocleidomastoid muscle. The cystic nature of a branchial cleft cyst can usually be determined. It is superficial, has a smooth surface, is freely movable, unless it is large or has been previously infected, and is not attached to any of the underlying tissues. Sinuses sometimes are associated with branchial cleft cysts if the cysts have been previously operated on and not completely removed. One should always inspect for a branchial cleft sinus or fistulous opening, which occurs along the anterior border of the sternocleidomastoid muscle usually just above the clavicle. The characteristic discharge is mucoid in type. A branchial cleft fistula has no cystic component as a rule. When the course of the tract is put under tension, a cordlike structure can be felt along the edge of the muscle.

Another lateral cystic lesion is a cystic hygroma, which often occurs in the lower portion of the cervical region, especially if it is small. If it is large, it may involve the entire neck. Such a lesion is cystic, soft and multilocular. A ranula is possibly a similar structure occurring in the upper portion of the neck. A ranula frequently can be identified by inspection of the floor of the mouth, where it shows as a watery bleb that disappears when punctured. Such lesions also can be felt in the submandibular region as cystic structures, usually bilateral.

Tumors of the Thyroid

Adenomas of the thyroid are frequently encountered. One should always be suspicious of a thyroid adenoma and should palpate the lateral aspects of the neck in all cases of nodular goiter for possible metastatic lesions. My colleagues and I consider that a nodular goiter is frequently enough malignant so that all nodular goiters should be removed. Whenever a node is found in the neck that has the characteristics of a metastatic lesion, the thyroid always should be carefully palpated. In our experience, about 4 per cent of nodular goiters that are not producing symptoms will contain unsuspected carcinoma.

Occasionally confused with a cyst of the thyroglossal duct is an adenoma of the pyramidal lobe of the thyroid gland. An adenoma may or may not be firm but rarely does it feel cystic. There is no palpable tract above an adenoma as is often noted with a thyroglossal duct cyst. Adenomas usually move up and down when the patient swallows and frequently the presence of other adenomas of the thyroid gland supports the diagnosis of this midline tumor as an adenoma.

Also to be confused with an adenoma of the thyroid gland or a cyst of the thyroglossal duct is a delphian node, which also occurs in this region. A delphian node is a metastatic lesion from a primary carcinoma in the thyroid. When the carcinoma is located in or near the isthmus, one of the first areas of spread is to a lymph node located over the thyroid cartilage; such metastatic lesions, however, are firm, usually small, and freely movable.

Tumors of the Salivary Glands

Tumors of the salivary glands are important in examination of the neck. A mixed tumor of the parotid gland will have been present for a long period; it is hard but yet as a rule it is freely movable unless it is in the deep portion of the gland. If a tumor that has been present for many years shows sudden growth, one has to be suspicious of malignant degeneration. The facial nerve is rarely involved regardless of the size of the tumor unless a malignant tumor is superimposed on the mixed tumor. However, a cylindroma, an adenocarcinoma, or another type of malignant tumor of the parotid gland is not only hard but is usually fixed within the tissue; such tumors frequently cause paralysis of the facial nerve, which is extremely important in evaluating a tumor and advising the patient regarding the treatment that should be carried out. Warthin's tumor, which is cystadenoma lymphomatosum, occurs in the parotid gland; it is soft, usually presents itself below or slightly behind the parotid gland and appears to be encapsulated on palpation. One should not confuse this lesion with a mixed tumor.

Miscellaneous Tumors

Among the primary tumors of the neck are tumors of the carotid body. These lesions occur in about the same area as do branchial cleft cysts but are deeper in the neck and are not cystic. Tumors of the carotid body may be elongated, extending upward and downward; because of their fixation to the carotid vessels, they can be moved laterally but not up and down, which is an important diagnostic finding. Lymphosarcoma occurs in a similar region in the upper part of the neck and in the lower portion of the neck in the internal jugular lymph nodes. Usually lymphosarcoma in the neck involves multiple nodes, frequently matted together. These nodes are usually rubbery in consistency.

A parathyroid cyst has to be considered occasionally, although this is a rare finding. A neurofibroma might occur along the lateral aspect of the neck under the sternocleidomastoid muscle. It is an elongated tumor in contrast to a lymphosarcoma, which is round or associated with a matted group of nodes. Neurofibromas frequently are bilateral. Lipomas are seen usually in the supraclavicular region and the posterior cervical triangle. They are soft and multinodular.

Inflammatory Lesions

Inflammatory lesions of the neck include acute lymphadenitis associated with respiratory and oral infections; this condition does not create a diagnostic problem since the enlargement of the nodes is of recent origin and usually bilateral. If, however, such lymphadenopathy does not disappear within two weeks, it should be regarded with suspicion. The chronic lesions of tuberculosis, sarcoidosis or other granulomas occasionally are confusing; biopsy is required to establish the diagnosis but one should be suspicious of this type of lesion from the history.

Metastatic Tumors of the Neck

Metastatic tumors in the neck are usually of recent origin and are firm and nontender. They may be movable but, if large, may be fixed to the surrounding tissues. Again, when one is suspicious that a tumor may represent metastasis to a node, careful search should be made for a primary lesion on the lip, in the oral cavity, or in the larynx, as well as on the skin of the face or scalp. Lesions of the lip spread in an orderly fashion to the submaxillary nodes in the neck. A node that is the seat of metastasis may be misleading if it has a necrotic center and feels soft. If a

Fractures of the Upper Extremity in Children

JOHN C. IVINS, M.D.
Rochester, Minnesota

FRACTURES in children are different than similar ones in adults. Ordinary good treatment produces better results in children than it does in adults. The heavy periosteum that surrounds the bone in children may help to prevent displacement; most of the time it makes for satisfactory manipulation and easier closed reduction. In preadolescent children, the potential for rapid growth will produce an excellent end result even after mediocre reduction. This same growth potential is responsible for the usual speedy union and the rarity of nonunion in children.

This generally optimistic outlook must be tempered by the knowledge that with improper treatment the complications of fractures in childhood can be disastrous. The general principles of treatment are not complex. Alignment is the chief requirement. While it is desirable to produce restoration of length and anatomic apposition, such restoration certainly is not necessary and failure to produce such a result is no indication for open reduction and internal fixation in children. As a rule, completely satisfactory results can be obtained by traction or by closed manipulation and immobilization in plaster. This rule, however, has the usual exceptions. Some fractures, notably certain types about the elbow, often require open reduction. In this discussion, I wish to consider the commoner major fractures of the upper extremity in children and to emphasize those that may be attended by complications or that require open reduction.

Fractures of the Humerus

Fractures of the humerus occur through the condyles, through the shaft, below the tubercles or through the upper epiphysis in about that order of freqency. Fractures of the shaft are rarely accompanied by palsy of the radial nerve and may be satisfactorily treated by application of a hanging cast. If the general alignment and rotation are good, one need not worry about end-to-end apposition or overriding and shortening of up to a half inch; sound union will occur and the proper length will be restored by subsequent overgrowth.

Separation of the upper humeral epiphysis may be treated the same way. Restoration of function and normal bony contours is usually rapid. If the epiphysis is completely displaced, manipulation with the patient under general anesthesia will be required, but even then one need not insist on strict anatomic reduction, and open reduction is rarely required.

Supracondylar fractures are common. Accurate reduction is difficult to achieve and even more difficult to maintain. Neural and vascular complications are more common than the physician usually suspects. Because of the close proximity of major nerves and arteries, in a typical supracondylar fracture the artery or one of the nerves may be impaled on the end of the proximal fragment or actually may be caught between the ends of the fractured bone. Once the diagnosis is established by initial roentgenograms, prompt treatment can be effective. Of prime importance is accurate evaluation of the patient's condition. Simple sensory and motor testing should be done to determine the status of the major nerves. The presence or absence of radial pulsation should be established; if it is present, one should note its quality. Closed reduction is then carried out with the patient under general anesthesia by traction in the long axis of the arm combined with flexion and pronation. It was formerly taught that these fractures should be put up in supination, but I believe the rotary components can be reduced best by putting the forearm up in pronation. Satisfactory reduction can be maintained only by means of a posterior plaster splint that holds the arm in flexion. If this causes dis-

appearance of radial pulsation, the elbow must be extended until pulsation reappears.

One can deal with these fractures by either continuous traction in bed or open reduction and fixation of the fracture by crossed Kirschner wires. Traction in bed will produce just as good results as will surgical intervention. The greatest danger is Volkmann's ischemic contracture, which presents pain as its most significant symptom. Never disregard the complaint of pain in the hand associated with these fractures. If this pain is accompanied by swelling, coldness, cyanosis or pallor of the fingers, prompt action must be taken regardless of the hour and regardless of the interval of time since the fracture. If extension of the elbow and removal of all circular dressings do not result in a prompt satisfactory return of circulation, block of the stellate ganglion by means of procaine might be considered. However, it is preferable to deal with this situation directly by opening the antecubital fossa and exploring the artery. The artery may be contused, transected or caught between the ends of the bone. Segmental resection of the damaged portion of the vessel relieves the reflex vasopasm and usually results in adequate circulation. Vascular grafting is not indicated in such cases.

Epiphysial Injuries at the Elbow

Epiphysial injuries at the elbow usually are more serious than the clinical picture or the roentgenograms would indicate. Three main centers of ossification are present at the inferior end of the humerus. One is for the lateral condyle, or capitellum, one is for the medial condyle, or trochlea, and one is for the internal epicondyle. At times, there may be a fourth center for the lateral epicondyle. A fall on the point of the flexed elbow may displace the entire epiphysis forward. Usually, however, the fall is on the outstretched hand and one of these centers of ossification is pulled away from the others by muscular traction. When the joint is forced into the varus position, the origin of the common extensor muscles on the back of the forearm may avulse the lateral part of the epiphysis, the capitellum, together with some of the adjacent portion of the trochlea and the end of the shaft. If the aponeurosis is incompletely torn, the condyle simply may be displaced laterally and not rotated. Such a fracture will unite firmly, with good results.

However, if the aponeurosis is completely torn, the condylar fragment may be rotated completely out of the joint and turned upside down. If the fracture is allowed to heal in this position, there will be an increase in the carrying angle and sooner or later ulnar palsy will appear because of stretching of the ulnar nerve. Open reduction is usually required. After the condylar fragment has been anatomically reseated in its bed, it usually can be held there firmly by suture of the surrounding soft tissues of the aponeurosis. Internal fixation of such a fracture is not required.

The epiphysis for the internal epicondyle does not unite until about the age of eighteen; thus, injury to this structure can occur until late in adolescence. Until that time, the origin of the common flexor muscles, which attaches to the internal epicondyle, may avulse this structure when a strain in the valgus position is applied to the elbow. This is an opposite strain from the one that has just been considered. At least four grades of such a displacement may occur. The least serious is a slight separation, with minimal displacement. The most serious is avulsion of the epicondyle associated with complete outward displacement of the elbow. The more serious displacements usually are associated with some damage to the ulnar nerve. Less extensive displacements may be adequately treated by closed manipulation, with immobilization of the elbow in the flexed position. However, when the avulsed epiphysis has been drawn into the joint it is necessary to do an open reduction, securing the fragment in its bed by means of a few sutures. An important point about the roentgenograms in epiphysial injuries is that the films may not tell the story at all as these structures are composed mainly of cartilage and are not well portrayed roentgenologically.

Children who fall on the outstretched hand may impact the head of the radius against the capitellum, causing displacement of the upper radial epiphysis. An important consideration here is that the head of the radius in children must never be excised. To do so will result in radial shortening, radial deviation of the hand and disruption of the radio-ulnar joint at the wrist. The usual displacement of the radial epiphysis can be treated by closed manipulation. When the displacement is more pronounced, it may be necessary to make a short incision and restore the parts under direct vision. In most cases, the epiphysis is perfectly stable after such a procedure. Occasionally, when it is not stable and will not stay in position, a Kirschner wire can be introduced from the back of the elbow through the capitellum into the shaft of the radius to hold its position for two or three weeks until early formation of callus occurs.

Fractures of the Forearm

Fractures of both bones of the forearm occur at the distal third, at the middle third and at the proximal third in about that order of frequency. Open operation is not justified for such fractures regardless of their level. It must be emphasized that no trace of angulation should be present in fractures of the proximal or middle third, for this will not correct itself with growth. Instead, permanent limitation of pronation and supination will result. Greenstick fractures at these levels frequently will be troublesome because of persisting and recurring angulation. In such situations it may be necessary to extend the greenstick fracture and convert it into a complete simple fracture in order to prevent recurring angulation. Some overriding is permissible if good alignment is attained.

Fractures of the upper third of the forearm should be immobilized in full supination and those of the middle third should be immobilized in midposition due to contraction of the muscles. It may be necessary to maintain alignment by using traction on the fingers and one need not fear doing this in children. Perfect restoration of the contours will be obtained in a few months and function as a rule will be normal.

Fractures about the distal third of the forearm may be left unreduced if the angulation is less than 30 degrees. The hazard of leaving such fractures alone is far less than the hazard of giving the patient an anesthetic agent and manipulating the fracture in any way. The distal fragments usually are displaced dorsally. In such fractures, there is a strong tendency for angulation to return even in a well-applied cast. Immobilization of such a fracture should be in a long cast with the elbow at a right angle and the forearm pronated. Molding of the cast is a more effective way of controlling the angulation than trying to put the hand way down in pronounced flexion. There is no justification at all for open reduction.

Fractures of the Hand

Space allows discussion of only one fracture of the hand. One of the common athletic injuries in adolescence is fracture of the neck of the fifth metacarpal. Such a fracture cannot be handled with the finger extended, because with such extension the ligaments are relaxed and the small distal fragment cannot be controlled. If the fracture is allowed to heal in this position, the end of the metacarpal will be down in the palm just like a marble. This type of fracture can be easily reduced, however, by flexion of the metacarpophalangeal joint to an angle of 90 degrees; after its reduction, it can be held that way by means of a plaster slab.

Conclusion

A plea is made for conservatism in treating fractures in children. Nature will do a wonderful job in healing these fractures and normal function will be restored, as a rule, if physicians will simply assist nature to the extent of restoring alignment and providing proper immobilization for an adequate length of time. In some cases, it is almost unbelievable to what extent nature will afford correction of extremely severe fractures in spite of minimal correction obtained at the time of manipulation.

SKIN CANCER

Sunlight may be a major cause of skin cancer. Five fields of evidence point to sunlight as a possible causative factor: "(1) Cancer of the skin of laboratory animals (mice and rats) can be induced by exposure to ultraviolet radiation; (2) cancer of the skin is more common among outdoor than indoor workers; (3) cutaneous cancer is less prevalent in Negroes than in the white races, presumably because the former are less susceptible to sunlight; (4) the incidence of cancer of the skin is greater in regions of the earth that receive high insolation; (5) cancer of the skin occurs principally on parts of the body most exposed to sunlight."—KETTERMAN, H. L.: Sunlight and cancer, *Journal of Kansas Medical Society,* 41:12 (Jan.) 1955.

Management of Recent Injuries of the Hand

PAUL R. LIPSCOMB, M.D.
Rochester, Minnesota

MANY excellent articles have been published about the injured hand. Much of the material included in this presentation was derived from articles published by the great pioneer in reconstructive surgery of the hand, Dr. Sterling Bunnell,[1,2] from a series of bulletins produced by the American Society for Surgery of the Hand[3] and from a recent article by Godfrey.[4] The accompanying sketches outline a plan of procedure that is applicable in the early management of the majority of injuries of the hand.

Wounds of the hand comprise 36 per cent of all industrial accidents. Although no accurate statistics are available, it is probably safe to estimate that a similar incidence is present in injuries around the farm and the home. If an injured hand is to regain useful function, it must be protected from infection and from additional damage to tissues, both of which may be instrumental in converting the hand into a rigid club. This protection is furnished initially by avoidance of meddlesome interference with the wound, cleanliness of the surrounding area, application of sterile protective dressings and immobilization in the position of function. Probing, examination, cleansing and treatment of the wound itself should not be undertaken until adequate surgical facilities are available.

Bunnell noted after examining thousands of crippled hands that six main types of crippling are encountered. These are (1) stiffening of the hand in poor position, (2) flexion contractures, (3) skeletal malalignment, (4) dysfunction from injuries to tendons and nerves, (5) ischemic contractures and (6) trophic or vasomotor conditions. Although the latter two types of crippling usually but not always are due to the initial injury, the first four types are often due to sins of omission as well as commission in the treatment of the injured hand.

Stiffening in Poor Position

Edema, together with immobility, is the commonest cause of stiffness. When these two factors are combined with a position of nonfunction after injuries to the hand, it will stiffen in its poor position. Edema results from many causes but especially from infection. In the presence of edema, fibrin is precipitated about the tendons, muscles and joints. Soon the fibrin is converted into rigid fibrous tissue and the hand becomes a club rather than a finely co-ordinated and delicate piece of machinery. Edema is prevented soon after the injury by elevation and use of compression dressings. These dressings must be voluminous and snug but not too tight. Active motion must be started as soon as it is feasible. The part that is fractured, burned or otherwise damaged must be splinted, but the remainder of the hand must not be immobilized but kept active and moving. The position of function of the hand is that of moderate dorsiflexion of the wrist, moderate flexion of the fingers and moderate abduction and opposition of the thumb. When injuries of the hand are treated, this position must be borne in mind constantly. If for some unpreventable reason the hand should partially stiffen in this position, all function is not lost, whereas if the wrist is flexed, the fingers are straight or clawed and the thumb is adducted, function is lost.

There is no place in the treatment of injuries of the hand for a splint that holds or allows the fingers to be maintained in the extended position. Even in mallet or baseball fingers, although the distal joint is hyperextended in treatment, the midjoint must be flexed so as to tighten the central slip of the extensor tendon and thus approximate the avulsed extensor tendon to the distal phalanx. In an extended finger, its intercapsu-

lar ligaments are relaxed and soon become fibrotic in this shortened position. In a flexed finger, the ligaments are tight.

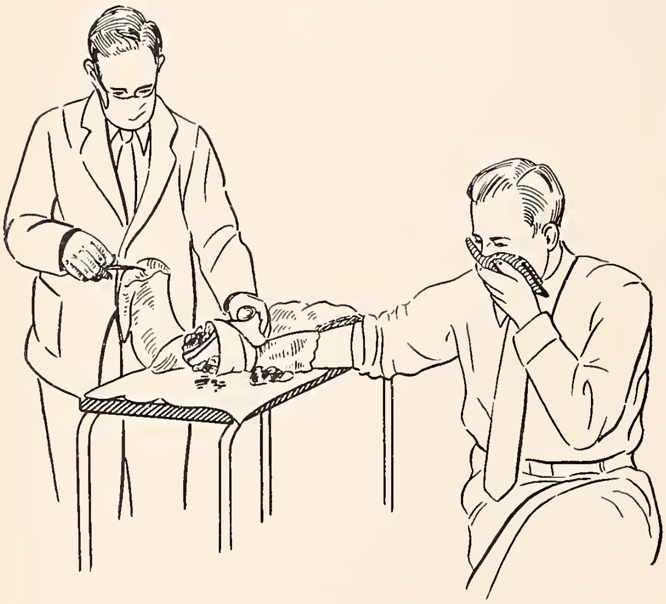

Fig. 1. Wounds of the hand should be covered immediately by a large protective sterile dressing. The nose and mouth of the physician or first-aid attendant and the patient should be covered in an attempt to prevent further contamination of the wound.

Infection as a Cause of Stiffening in Poor Position.—Infection produces edema, pain on motion and thus immobility and a poor position, which is assumed for protection. Therefore, all possible precautions should be taken to prevent infection. A mask should be worn by all who come in contact with an open wound of the hand (Fig. 1). A large protective sterile dressing should be applied to the hand immediately after injury. The wound should not be probed or fully examined until this large first-aid dressing is removed and all arrangements have been made to proceed with the necessary surgical care (Fig. 2). The patient must be taken to the hospital immediately, as time is an important factor in preventing infection.

It is unsafe to repair deep structures in a wound of the hand if bacteria have had an opportunity to multiply for more than 8 to 10 hours after injury. The wound should be gently but thoroughly cleansed with soap and water and then completely excised or débrided; tendons, nerves and bones should be carefully preserved (Fig. 3). Fresh wounds have nonvirulent contamination and heal well if circulation, closure, compression dressings and rest are adequate. Tendons and nerves should not be repaired primarily in crushing, explosive or grinding injuries.

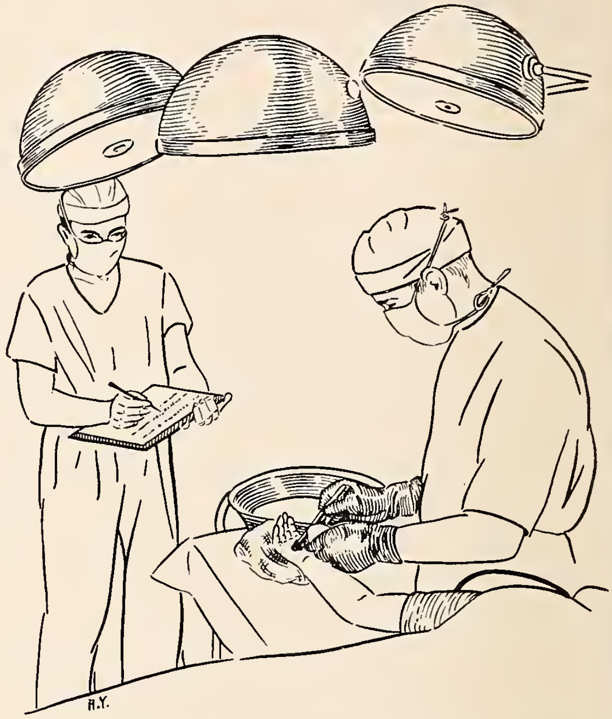

Fig. 2. The first-aid dressing is not removed nor is the wound thoroughly inspected until the patient is in the operating room and plans have been made to proceed as necessary. Careful evaluation of the injury is then made and recorded and a plan of reconstruction is decided on. The hand and forearm are shaved, washed with soap and water and the wound is thoroughly irrigated with normal saline solution. A pneumatic-cuff tourniquet is applied.

Every effort should be made to attain effective and early closure of the wound. The rotation of flaps of skin and grafting of the donor site, using the skin of a filleted finger or an immediate pedicle flap from the abdominal wall, may be necessary (Fig. 4). Thus, months of drainage from infection and its concomitant crippling may be avoided. Especially is it important to cover all vulnerable parts such as joints, bones, tendons and nerves, which are so suspectible to infection. On the other hand, the closure must not be under tension. If a wound is too dirty to close, it may be packed open for five to seven days and closed secondarily.

Flexion Contractures

Flexion contractures are due to contracted scar tissue resulting from a burn or an open infected wound. Prevention, therefore, involves utilization of all available means to close the wound. In burns, the deep bed is usually in good condition for grafting. Often the burn has become demarcated to such an extent that the destroyed skin can be excised four or five days after injury and a split-thickness skin graft can be applied at the same time or a few days later. Granulation tissue, if present, should be scraped off so as to apply the skin on a good bed that will not contract later. The borders of either a free or a pedicle graft should be zigzag and should not cross a flexion crease in a straight line. The hand and wrist must be splinted in a position of function if contractures are to be avoided (Figs. 5 and 6).

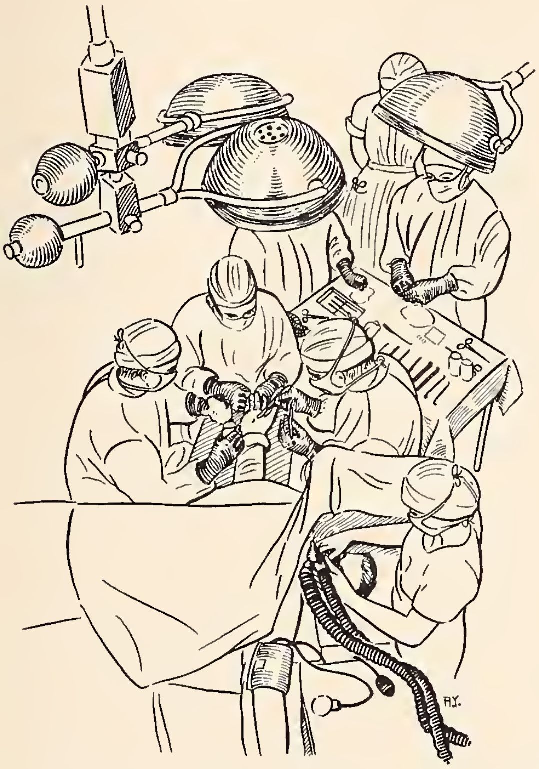

Fig. 3. Definitive treatment requires a well-equipped operating room, good lighting, adequate instruments, sufficient assistance, complete anesthesia and a bloodless field as supplied by the pneumatic tourniquet. Strict asepsis, with use of masks, gowns and gloves, helps prevent contamination of the wound with more virulent organisms. The wound is thoroughly débrided but all usable parts are saved, especially nerves and tendons. Fractures are reduced, the digits being placed in the position of function so they will be opposable.

Skeletal Malalignment

Skeletal malalignment must be prevented by restoration of normal function of the bony structures at the earliest possible time. Restoration of normal position is accomplished by manipulation, skeletal traction or open reduction. Regardless of whether a fracture or a dislocation is being manipulated, full relaxation, preferably induced by having the patient under general anesthesia, is desirable. Manual traction, pressure and molding should be performed gently and deliberately to avoid further injury to soft tissues. If reduction is not promptly successful, operative (open) treatment is in order, since less harm is done by gentle surgical procedures performed through a correct incision than by rough and forceful closed manipulation.

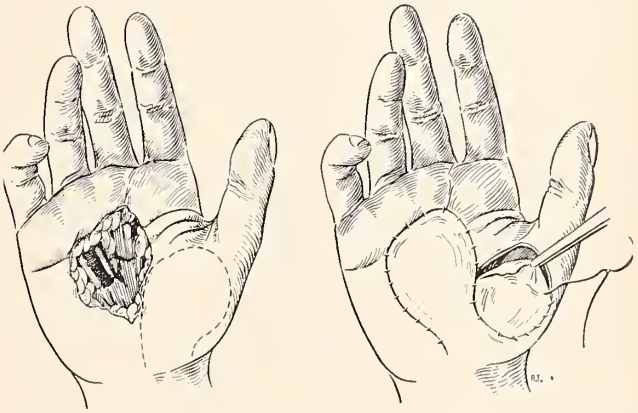

Fig. 4. A cover of skin is supplied if at all possible, and usually it is, by swinging a flap as illustrated and applying a split-thickness graft to the resultant defect, by application of a split-thickness graft directly to the defect in selected instances or by use of a direct pedicle graft from the abdominal wall. If a finger has to be discarded, its skin with vessels and nerves may be utilized for cover.

To maintain reduction, particularly of oblique or comminuted fractures of the phalanges or metacarpals or fractures into joints, control by skeletal fixation may be required. The hand and the injured finger or fingers should be supported in the position of function. Not much traction is needed for fractures of the metacarpals and phalanges. The pull must be applied with the finger held semiflexed and never straight. Use of banjo splints is to be condemned. Rotary malunion of digits is avoided by checking to see that the plane of motion of each finger passes through the navicular tubercle and by observing the plane of the nail. Stiffening of adjoining fingers is avoided by splinting only the one that is injured. All uninjured parts must be kept moving. The cast should hold the wrist in dorsiflexion; it must be molded to the metacarpal arch and should terminate at the distal flexion crease and the thenar crease in the palm so that the proximal finger joints are free to flex.

For many metacarpal fractures, temporary pinning with Kirschner wires cut off beneath the skin to avoid infection is an excellent method of fixation; the hand does not stiffen, as it is not in a cast. The wiring or plating of fractures of the bones of the hand generally is unsatisfactory. Healing of fractures of the long bones of the hand requires immobilization for three to five weeks; healing of fractures of carpal bones requires twelve to fourteen weeks. Fractures of the navicular may require four months for union. If immobilized consistently for these periods, most of these fractures will not require surgical intervention.

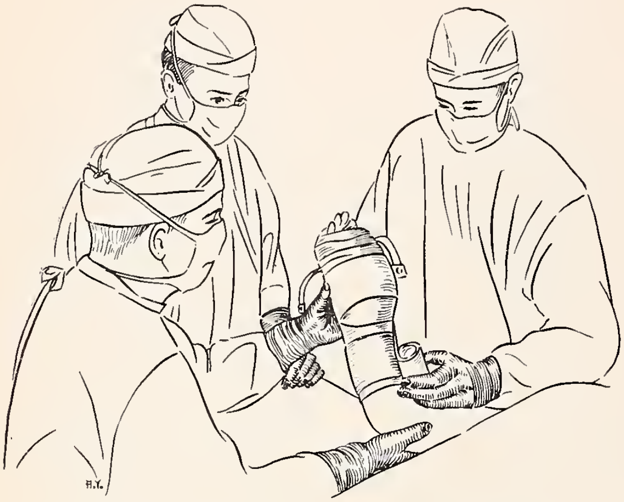

Fig. 5. Swelling is avoided by fluff compression dressings that are applied just tightly enough, but not too tightly, to the hand, which is in the position of function with the finger tips exposed so that circulation may be evaluated. Straps for elevation are incorporated in the dressing.

Injuries to Tendons and Nerves

The dysfunction from injuries to tendons and nerves is best prevented by repairing these structures early, within a few hours, and establishing a good cover of skin. Success depends on obtaining primary healing. In wounds more than eight to twelve hours old or in badly contaminated, dirty or explosive wounds, primary repair of tendons and deep structures must be omitted or serious infection will follow. The surgical repair must be done through proper incisions, with minimal trauma. The best conditions for healing are accomplished by avoidance of dead spaces, hematomas, buried sutures, especially catgut, and tight suturing. For the average surgeon it is best to unite the ends of nerves with one suture of stainless-steel wire or silk to prevent retraction of the ends, thus facilitating secondary resuture under the best of conditions later. However, when primary suture of a nerve is performed expertly, the regeneration is sooner and better than that obtained after late repair. Nerves can and should be successfully repaired down to the distal flexion crease in the finger, including even the tiny motor branches within the hand. Injury to the nerves in the arm or brachial plexus is just as crippling as is injury to the hand itself and repair of these nerves should take precedence over that of bones and joints. When this is not done, the paralyzed muscles and distal portions of the nerves undergo such irreversible fibrous atrophy that restoration of function is impossible. A paralyzed hand needs to be kept mobile and in the position of function or it becomes a useless claw in a position of nonfunction. The patient should be instructed to keep the paralyzed hand in the position of function by gently manipulating it with the good hand. Painful and tender neuromas are avoided by minimizing formation of scar tissue. Amputation should be done in noninfected fields and the endings of nerves placed in good tissue.

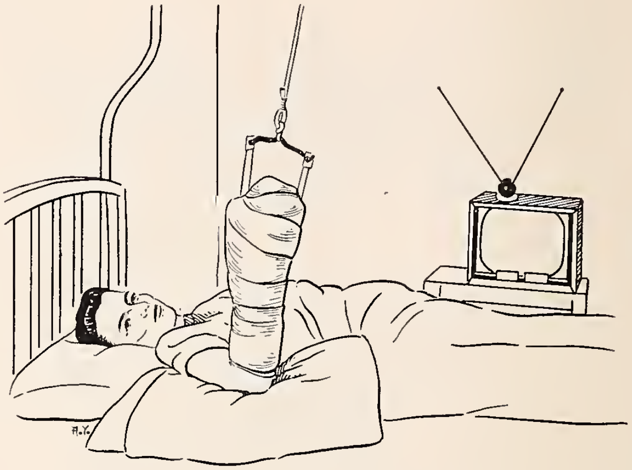

Fig. 6. The bandaged hand is elevated and rest is enforced until the acute reaction of the injury is past, which usually takes about three days.

Ischemic Contractures

Ischemic contractures, both of the Volkmann type and the local type in the hand, usually are preventable by avoidance of tight casts or dressings. If the patient continues to complain of severe pain a few minutes after the cast or dressing is loosened and if there is evidence of impaired circulation in the hand, emergency surgical treatment is necessary if the severe crippling that results from prolonged ischemia is to be avoided.

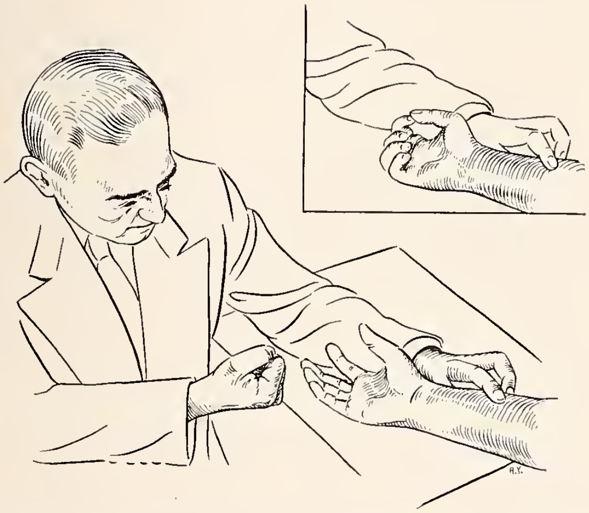

Fig. 7. Supervised active, not passive, motion not only of the uninjured parts but also of the injured part must be started as soon as healing will permit.

Trophic or Vasomotor Conditions

Some patients appear more inclined to experience so-called Sudeck's atrophy and the tendency to causalgia than do others. These persons usually have unstable sympathetic nervous systems. Early recognition of such patients and encouragement in whatever activity may be required to make these people use their hands during every waking moment usually will abort the development of this extremely painful and disabling complication (Fig. 7).

Summary

Review of the six main types of crippling of the hand, namely stiffening in poor position, flexion contractures, skeletal malalignment, loss of motion and sensation from injuries to tendons and nerves, ischemic contractures and trophic or vasomotor conditions, leads to the conclusion that many of these complications can be ascribed to treatment and, therefore, are preventable.

TUMORS OF THE NECK

(Continued from Page 295)

tumor is invading surrounding structures, it may be tender and make the examiner think of an inflammatory lesion.

If a patient has a hard, nontender node or nodes in the lower deep jugular region or supraclavicular region (Virchow's, or sentinel, node) on the left, one must be suspicious that these are secondary to a primary tumor of the lung, stomach or kidney.

Incision for Lesions of the Neck

In removal of a tumor of the neck for examination, it is extremely important always to use a transverse rather than a vertical incision. A transverse incision heals nicely and is not a cosmetic problem later. Any incision that is made vertically in the neck crosses the natural cutaneous lines and results in a puckered scar. For a large tumor in the neck or when an extensive resection is being done, such as a radical dissection of the neck, a vertical component to the horizontal incision is usually necessary.

Comment

Regardless of how careful the examiner may be, his impression of a tumor of the neck is just a guess until he proves the diagnosis by biopsy. Since many of these tumors are malignant, cosmetically deforming and potentially infected, all should be surgically investigated when discovered. The attitude, "The tumor is not bothering you, why bother it?" should not prevail.

Precautions in the Use of Cortisone for Treatment of Rheumatic Diseases

L. EMMERSON WARD, M.D.
Rochester, Minnesota

CORTISONE and related hormones, such as hydrocortisone and corticotropin, are the most potent antirheumatic agents known at present.* Unfortunately, these hormones also are capable of producing metabolic effects that often are undesirable and, indeed, sometimes temporarily harmful, especially if excessive doses are employed.

For optimal results, the use of these hormones in the treatment of rheumatic diseases must be attended by certain precautions, which can be divided into three convenient categories: (1) selection of the proper disease for treatment, (2) selection of the proper patient having one of these diseases, and (3) selection of proper dosage and attention to other details of management during treatment.

General Precautionary Measures

Selection of the Rheumatic Disease.—Cortisone is most commonly indicated in selected cases of the following rheumatic diseases:

1. Rheumatoid arthritis and its variants, such as rheumatoid spondylitis, Still's disease, Felty's syndrome, Reiter's syndrome, psoriatic arthritis and the arthritis associated with chronic ulcerative colitis.
2. Acute rheumatic fever.
3. Systemic lupus erythematosus.
4. Periarteritis nodosa.

In a second group of diseases cortisone occasionally may be helpful but its systemic administration is usually not indicated, since other and simpler measures ordinarily suffice. These diseases include:

1. Arthritis of hypersensitivity states, such as serum sickness, in which antihistaminic drugs, epinephrine, salicylates, local application of heat, and rest for the affected joints usually are adequate.
2. Acute gouty arthritis, for which colchicine is the drug of choice.
3. Acute nonspecific bursitis, tendinitis and the shoulder-hand syndrome; for these conditions, physical medicine, salicylates and, in certain cases, roentgen therapy or local injection of hydrocortisone generally are sufficient.

Cortisone should not be employed for:

1. Specific infectious (septic) arthritis.
2. Osteoarthritis.
3. Primary fibrositis.
4. Psychogenic rheumatism.

In osteoarthritis of peripheral joints, intra-articular injection of hydrocortisone may produce temporary symptomatic relief and is often useful, especially for acute or subacute flare-ups, but prolonged systemic administration of cortisone should be avoided.

Selection of the Patient.—If it has been established that a co-operative patient has a disease for which cortisone may be indicated, the next decision concerns the suitability of its use in the particular patient. Two principal considerations arise in this regard. The first is whether the disease in this particular instance is of sufficient activity and severity to warrant the use and expense of hormonal therapy or whether the patient would respond equally well to simpler treatment. For example, many patients who have mild rheumatoid arthritis can be managed satisfactorily by a general program, such as physical therapy, salicylates, extra rest, protection of joints and other supportive measures. Secondly, does the patient have some other condition that might be aggravated by cortisone and that, therefore,

*Reference will be made primarily to cortisone in this presentation, although the remarks apply generally to hydrocortisone or corticotropin.

might contraindicate its use? Absolute contraindications to prolonged usage are psychoses, Cushing's syndrome, and tuberculosis and certain other infections not readily susceptible to control by currently available therapeutic agents, as acute poliomyelitis. Relative contraindications include renal and cardiovascular insufficiency, peptic ulcer, psychoneuroses, osteoporosis, diabetes mellitus, convulsive disorders and certain severe intercurrent infections.

The decision of whether or not to employ cortisone in the presence of one of these relative contraindications requires balancing the possible benefits of cortisone against its possible hazards in each particular patient. For example, one might elect to avoid use of cortisone if a patient has a moderate degree of rheumatoid arthritis but a peptic ulcer that is difficult to control, whereas one might employ cortisone for severe, incapacitating active rheumatoid arthritis in the presence of a peptic ulcer that could be controlled by careful medical management. Occasionally, the pros and cons are so evenly balanced that only cautious trial of treatment may allow a definite decision.

Selection of Dosage and General Management. Studies Prior to Treatment.—Before cortisone is used, the patient should receive a complete medical examination, a roentgenogram of the thorax, serologic tests for syphilis, urinalysis, determination of hemoglobin and leukocytes in the blood and other tests pertinent to evaluation of the disease or complicating conditions. The physician should discuss thoroughly with the patient the potentialities and limitations of treatment with cortisone and should stress the necessity for frequent rechecks and co-operation in following directions carefully.

Choice of Hormone.—Doses of cortisone, hydrocortisone or corticotropin required to produce equivalent antirheumatic effects differ somewhat. On the average, the required amount of hydrocortisone given orally may be about 20 per cent less than that of cortisone, although in practice individual variations are considerable.[1,2] It is even more difficult to estimate comparative doses of corticotropin owing to differences that result from such factors as the preparation used, the route of administration and the variable activity of the adrenal cortices. However, increased antirheumatic activity of these hormones is accompanied by increased metabolic activity, affecting electrolytes, water, protein, fat and carbohydrate. No one of these three hormones has proved consistently superior to the others in the avoidance of hypercortisonism.

Examination During Treatment.—During administration of the hormones, the patient should be examined periodically with regard to the effect of treatment on control of the disease and to the presence or absence of hypercortisonism. The frequency of periodic rechecks depends on the disease and the individual circumstances. The patient who is treated for acute systemic lupus erythematosus with large doses of cortisone needs to be checked clinically at least daily; laboratory tests, such as urinalysis and measurement of serum electrolytes, sedimentation rate and hemoglobin, may be required frequently. On the other hand, the rheumatoid patient treated with small doses of cortisone may need to be seen only at weekly intervals initially, then later at intervals of two to four weeks, at which time the clinical status should be evaluated carefully and weight and blood pressure recorded; necessary laboratory tests may be minimal, such as urinalysis and measurement of hemoglobin and leukocytes every two or three months, and roentgenograms of the thorax every six to twelve months.

Careful clinical observation of the patient is of more importance than are laboratory tests in the management of the patient receiving cortisone, especially in the detection of hypercortisonism. Such evidence of hypercortisonism as mental stimulation, increased appetite, gain in weight, facial rounding, retention of fluid and appearance of supraclavicular fat pads usually occurs long before any laboratory signs of hypercortisonism.

Regulation of Dosage.—Regulation of dosage is the most important phase of careful treatment. Attitude toward dosage should be conditioned to a great extent by the disease under treatment and the anticipated duration of hormonal therapy.

For acute self-limited but potentially damaging diseases, such as acute rheumatic fever, relatively large doses are employed to accomplish quick suppression of the inflammatory reaction; then a gradually lowered but completely suppressive dose is maintained for the relatively brief course of the disease. For example, one might give to a young adult with acute rheumatic fever 200 or 300 mg. of cortisone daily for a few days until clinical signs of acute rheumatic fever have disappeared, after which the dose might be reduced to about 100 to 150 mg. daily for the next two or three weeks. Then slightly lower doses, perhaps 50 to 100 mg. daily, might be employed for the next few weeks. Thereafter the dose might be tapered off in a period of another week or two or longer if necessary. Recurrence of activity may call for temporary increase in doses. Signs of hypercortisonism in the presence of apparently complete suppression of the disease would indicate the probable desirability of some reduction in dosage. Obviously, dosages and duration of treatment should be adjusted to the needs of the individual patient; the variation in severity and duration of the disease does not permit a routine schedule of treatment. When such large doses as just outlined are employed, a low-salt diet and the administration of potassium chloride (for example, 2 gm. three times daily) are advisable.

For subacute and chronic diseases typified by occasional acute, potentially fatal flares, as for example in systemic lupus erythematosus, extremely large doses of 300 to 1,000 mg. or more per day may be employed temporarily during the acute stages; subsequently the dose is tapered off so that during the chronic stages little or no cortisone is employed. If the use of cortisone is necessary during the less acute stages, the dosage should be regulated to avoid hypercortisonism in much the same manner as will be described in the discussion of rheumatoid arthritis.

For chronic diseases requiring indefinitely long treatment, as in chronic rheumatoid arthritis, the dose should be kept low enough to avoid hypercortisonism.

Dosage in Rheumatoid Arthritis

The objective in the treatment of rheumatoid arthritis with cortisone or related hormones should be to achieve as much antirheumatic effect as possible without producing hypercortisonism.

Problems of Chronic Hypercortisonism.—If large doses of cortisone, hydrocortisone or corticotropin are administered to a rheumatoid patient, antirheumatic effects may be maintained whether or not signs of hypercortisonism appear. However, in some patients maintenance of excessive doses producing hypercortisonism eventually leads to serious complications, such as osteoporosis with fractures, peptic ulcers, pronounced emotional disturbances and excessive retention of fluid. Extreme fatigability, emotional lability and depression and diffuse aches and pains unlike but often confused with rheumatoid symptoms may be noted.[4] Reactions simulating systemic lupus erythematosus or periarteritis nodosa have occurred in several cases.[5] At present, one cannot predict in which patients significant complications will develop if hypercortisonism is permitted to persist. Therefore, doses should be regulated to avoid hypercortisonism in all patients.

Policy on Dosage.—A policy of restriction of dosage so as to avoid hypercortisonism implies that doses will be smaller than those employed previously by many physicians. As a consequence, less than complete antirheumatic effects may result in many cases. Necessary compromises in dosage may permit suppression of only 50 to 75 per cent of symptoms. Relief of this or greater magnitude generally can be achieved in at least 50 per cent of cases, often more easily in men than in women. In about 35 per cent of cases satisfactory regulation of dosage may be more difficult, while in about 15 per cent continuous adequate control of rheumatoid arthritis with tolerable doses is difficult or unsatisfactory.

Initial Doses.—My colleagues and I virtually have eliminated the use of large initial priming doses in our present treatment of rheumatoid arthritis. Starting doses are the approximate amount estimated as reasonable for prolonged maintenance, governed by the activity of the inflammatory reaction and the patient's expected susceptibility to hypercortisonism. The following daily doses of cortisone often are employed initially: for men, 40 to 60 mg.; for postmenopausal women, 20 to 30 mg.; for other women, 25 to 40 mg. Doses of hydrocortisone are slightly less. Sometimes the chosen initial dose may prove insufficient, in which case a small increment (5 to 10 mg.) may be made temporarily.

Reduction of Dose.—As soon as antirheumatic response is definite, gradual reduction of dose is attempted. Decrements generally are from 2.5 to 5 mg. when the dose is 50 mg. or less, or from

5 to 10 mg. when the daily dose is more than 50 mg. If a previous reduction has been well tolerated, the dose may be reduced again within a week or so. In some patients, reduction must be made less often. If the response to the previous reduction has been less favorable, another decrement may be delayed for several weeks or as long as necessary for the patient to readjust to the new dose, unless further reduction is dictated by other circumstances, such as the presence of hypercortisonism.

Maintenance Doses.—The maintenance dose is not a fixed dose. Ideally, it is that variable and usually decreasing amount required to maintain relief without producing hypercortisonism. Thus maintenance refers to relief, not dose. The proper dose for maintenance of relief varies from patient to patient and from time to time in the same patient; hence, frequent individual attention is required. Occasional and repeated attempts at reduction should be made even though the patient appears to be well stabilized at a given dose, since a smaller dose may accomplish as much. If the reduced dose proves insufficient, the former dose can be reinstated, perhaps for one to three weeks or so, before reduction is again attempted. Eventual discontinuation of medication by gradual reduction should be the aim.

For mild or moderate flares, the dose often can remain unchanged; extra amounts of acetylsalicylic acid, physical therapy and rest may suffice. If necessary the dose may be increased by 5 mg. for mild or moderate flares and 10 mg. for more severe flares; a second increment may be given later if required. The dose is reduced again as soon as the flare begins to recede.

Experience suggests that daily doses for prolonged treatment generally should not exceed the following limits: for men, 50 to 60 mg.; for postmenopausal women, 30 to 35 mg.; for other women, 40 mg. Hypercortisonism develops in some patients who receive less than these doses; others can tolerate slightly larger doses. In case of increased stress or pronounced articular flare, temporary use of larger doses may be required.

Division and Spacing of Daily Oral Doses.—For most patients the daily oral dose of cortisone should be divided into four more or less equal parts and one part should be given every six hours; a typical schedule might be 10 mg. at 6 a.m., noon, 6 p.m., and midnight. The duration of antirheumatic effect of cortisone sometimes is sufficiently long to permit the patient to take the last dose of the day at bedtime rather than having to be roused from sleep to take the final dose at a later time.

Other patients may be treated more satisfactorily by varying the size of individual doses during the twenty-four-hour period so as to provide a little more cortisone for times when symptoms are likely to be worse. Thus, for a man whose symptoms are particularly severe during the morning but much less severe in the afternoon and evening, a program of 20 mg. at 6 a.m. and 10 mg. at noon, 6 p.m. and midnight may achieve better results than a program of 12.5 mg. every six hours, although the total dose would be the same in each instance.

Flexible Program of Dosage.—Many rheumatoid patients experience varying degrees of symptoms from day to day during an average week. For some such patients it may be better to employ a flexible program in which the patient takes a slightly different amount for "average" days, "good" days and "bad" days. Thus, instead of a daily maintenance dose of 45 mg. during the week (total weekly dose of 315 mg.), such a patient might more effectively take 40 mg. daily for three average days, 35 mg. daily for two good days and 45 mg. daily for two bad days (total weekly dose of 280 mg.). Such a program not only supplies more cortisone when needed but also reduces the amount given at times when less is required. In this way smaller total doses may be successfully employed. This plan requires especially intelligent co-operation by the patient, as well as careful check by the physician to insure that supplemental doses are not employed excessively or unnecessarily. The patient is not permitted to regulate his own dosage but rather is permitted a choice within a slight range of dosage predetermined by the physician.

Supplementary Measures.—Appropriate supplementary treatment, such as physical therapy, salicylates, adequate rest, protection of involved joints and other supportive measures, should be continued during administration of cortisone.

Management in Case of Stress

The pituitary-adrenocortical mechanism is inhibited by long-term treatment with cortisone or corticotropin and, therefore, it cannot react normally to produce increased quantities of needed adrenocortical hormones in case of stress. Thus, in order to prevent the serious consequences of adrenocortical insufficiency in severe stress, sufficient additional hormone must be administered.[3,6,7] For minor stress, such as a mild intercurrent infection or a minor surgical procedure performed with the patient under local anesthesia, the maintenance dose of cortisone should be continued or rarely increased slightly, perhaps by 25 to 50 mg., for the duration of the stress; careful clinical observation should reveal any need for additional cortisone.

In major stress, such as a major surgical operation, serious injury or severe intercurrent infection, even more additional cortisone must be given. In elective major surgical treatment, my colleagues and I give 200 mg. of cortisone intramuscularly forty-eight hours, twenty-four hours and one hour before operation. On the day after operation, 100 mg. is usually given if the patient's condition is satisfactory; within the next two to three days the dose is gradually reduced to the preoperative maintenance level or its use is discontinued. Oral administration is resumed postoperatively whenever it is conveniently possible.

For more urgent surgical procedures or other emergencies, 200 mg. or more of cortisone is given intramuscularly as soon as possible; this dose is repeated after operation and as needed thereafter. In addition, a dose of 100 to 200 mg. of hydrocortisone in solution is given intravenously in 250 cc. of isotonic solution of sodium chloride during operation or for rapid effect in other emergencies, to be repeated as needed during or after operation.

Other precautions also are advisable to minimize the effects of major stress in these cases. Operation should be performed early in the day to avoid prolonged fasting and other stress incident to waiting. If intravenous administration of fluids is required, the use of glucose alone in distilled water should be avoided; isotonic solution of sodium chloride or such a solution containing 5 per cent glucose should be used instead. Morphine is poorly tolerated by patients who have adrenocortical insufficiency; the use of meperidine hydrochloride (demerol hydrochloride) appears preferable.

During and after operation or other stress, the patient should be watched closely. Blood pressure and pulse are checked at least hourly for twenty-four to thirty-six hours. If signs of adrenocortical insufficiency develop, such as weakness, tachycardia, hypotension, vascular collapse or respiratory failure, 100 to 200 mg. of hydrocortisone should be promptly administered intravenously in 250 cc. of isotonic solution of sodium chloride; this injection should be repeated as often as necessary to maintain normal blood pressure. A dose of 200 mg. of cortisone should also be given intramuscularly for later supportive effect. Oxygen, blood transfusions and vasopressor drugs, such as norepinephrine, 4 mg. in isotonic solution of sodium chloride, may be employed as indicated if shock develops.

The afore-mentioned precautions are employed not only for patients currently under treatment with cortisone but also for those who have received significant amounts of the hormone within the past three to six months, or even within the past year if hypercortisonism has been present. In patients treated with cortisone less recently, prophylactic use of cortisone often is deemed unnecessary. However, in such cases the other precautions just described are observed just as in the case of the patient who receives cortisone, and a solution of hydrocortisone is kept available for emergency intravenous use.

Patients treated with cortisone or related hormones should carry cards similar to those carried by diabetic patients to inform those who might care for them in an emergency that special care and additional doses of hormone may be required.

Conclusion

This presentation purposely has stressed the possible hazards and necessary precautions during administration of cortisone in the treatment of certain rheumatic diseases. In viewing these hazards, one must not overlook the benefits that result from use of cortisone in certain carefully selected, properly managed patients who have one or another of the rheumatic diseases for which

Digestive Ailments of Older Patients

ALBERT M. SNELL, M.D.
Palo Alto, California

AN AGING population is rapidly developing and more patients are living longer and remaining in better health at present than at any time in history. Among this group, gastrointestinal complaints are extremely common and varied. The literature bearing on the field of geriatric gastroenterology is scanty and individual experience is limited. Since degenerative cardiovascular renal disease and cancer loom so large as causes of death, it is natural that the bulk of the literature on the aging process has concerned itself with these two problems while the gastrointestinal tract has been almost forgotten. Only in recent years have gastroenterologists become interested in this problem. Those who have written about it have agreed in emphasizing (1) the fact that many of the gastrointestinal complaints are due to curable or correctable lesions, (2) the variation in symptomatology from the usually accepted classic clinical syndrome of the disease in question and (3) the opportunity which the family physician has in dealing with this group of patients.

The Pathologic Physiology of Aging

The changes which occur in various organs of the body as a result of the aging process have been fairly well documented, the exception being the gastrointestinal tract. There are minor degenerative changes of the salivary glands with a reduction of ptyalin secretion. Since digestion of starch begins in the mouth, these changes may be reflected in the development of fermentative diarrhea. The esophagus itself is usually seen to resist the passage of time but in some very old persons there may be either atony or unco-ordinated peristalsis with resulting dysphagia. The lowering of gastric acidity with age has been well studied and it is probable that about 10 to 12 per cent of older persons have permanent anacidity. Some atrophy of the gastric mucosa has been reported but this finding has been contradicted by recent gastroscopic biopsy studies that show essentially normal mucosal structure in the stomachs of many older people. Radiologists tell me that there is little evidence of a loss of gastric tone or motor activity in the aged. So far as the small intestine is concerned, the little that is known about it would indicate that no significant changes take place in it as a result of aging. The same statement cannot be made of the colon, in which loss of muscle tone and propulsive activity is frequently seen. This problem is frequently compounded in older persons by the development of rectal lesions that interfere further with normal intestinal function.

So far as the accessory organs of digestion are concerned, some falling off in organ weights may occur but little else has been observed. The liver may show some abnormal pigmentation of its cells and fibrosis around the portal spaces but the cell mass as a whole appears to be normal and such liver functional data as exist would indicate that the physiologic capacity of the liver is not greatly disturbed. Much the same statement can be made with regard to the pancreas.

With regard to the abdominal vasculature, aging may be a basis for such lesions as mesenteric thrombosis. However, existing evidence appears to indicate that degenerative vascular disease of the abdominal aorta and its branches lags somewhat behind the same changes in other portions of the body.

I shall have relatively little to say about cancer and will, in the main, deal with the benign gastrointestinal diseases, for many of which there are satisfactory and acceptable forms of treatment.

Case-taking in Geriatric Gastrointestinal Disease

As in pediatrics, diagnoses in old patients must be based largely upon objective evidence and upon a sound general knowledge of what is likely

---

Read at the meeting of the Minnesota Academy of General Practice, Rochester, Minnesota, October 20, 1954. From the Palo Alto Clinic.

to be wrong. The histories in older patients, almost all of whom have some digestive complaints, may be grossly misleading. Many elderly individuals are willing to blame their complaints on "something I ate," upon supposed allergies and upon other ailments that they have been known to have for a long time. Many of them probably minimize their symptoms because they are afraid of what might be found. Finally, many of them are unwilling to discuss the personal, social and economic difficulties which may play a large part in the production of their symptoms. For this reason one may recommend the general practice of first getting acquainted with the patient, then seeing what else is wrong with him (since multiple diagnoses are the rule in the aged), and finally considering the gastrointestinal complaints.

The well-established practice of obtaining a history of the complaints for a single typical day is helpful; of even greater value is the presence of a relative or friend who may often supply the pertinent details. Finally, it is wise to make an attempt to see any acute episodes of distress which these oldsters may have. A visit to the old man or woman in the patient's own home and the observation of an episode of the illness at first hand may be of greater value than even the most detailed studies in the hospital. The advantages that the family physician has in respect to these factors are obvious.

Common Gastrointestinal Diseases of the Aged

I shall attempt to refrain from statistics so far as is possible. However, I have drawn freely upon Monroe's experiences at the Geriatric Clinic of the Peter Bent Brigham Hospital, upon some observations kindly made for me by Dr. Roger Egeberg and his colleagues at Wadsworth Hospital in Los Angeles and upon the personal experiences of some of my own colleagues. It seems well to begin at the entrance to the digestive tube.

Diseases of the Esophagus.—There are probably more erroneous diagnoses made in respect to esophageal disease than any other field of gastroenterology, the reason probably being that it is not often recognized how frequently esophageal disorders will produce symptoms referable to the abdomen. Cardiospasm is a relatively rare condition in older persons, but carcinoma is common enough and should be the first consideration in any elderly person with a short history of dysphagia. Both of the former are overshadowed in importance by one common ailment, namely, hiatus hernia, with or without peptic esophagitis. Such hernias are common in old people; in fact, evidence indicates that there may be a relative relaxation of the esophageal hiatus which increases with age. The diagnosis frequently can be made from the history alone, the most common feature of which is nocturnal or postural pyrosis and regurgitation of food, along with varying degrees of transitory dysphagia and of pain in the epigastrium and left upper quadrant. The diagnosis is clinched by roentgenologic study. If one is to get maximal help from the radiologist, however, one must tell him what is suspected.

It is remarkable how often older patients with hiatus hernias are admitted to the hospital with a history of bleeding; probably at least a third are anemic when first seen. Actual esophageal ulcers are not infrequently seen when they are sought for, usually in the herniated portion of the stomach or in the distal portion of the esophagus. Probably patients can bleed from esophagitis and gastritis alone without gross ulceration.

Diverticula of the esophagus are not especially rare. It is noteworthy that they infrequently cause symptoms until the later years of life. The important diverticula to identify are those at the pharyngo-esophageal juncture. Such diverticula, when filled with food, may set off a chain reaction of aerophagia and belching; hyperventilation may be associated with the condition as well. Auscultation of the neck during the act of deglutition may be of diagnostic value.

Traction diverticula of the middle third of the gullet are of lesser importance, while those of its distal portion are extremely rare. It is important to exclude esophageal lesions in patients who have supposed cardiac disease. Barium studies, so widely used by radiologists in studying the outlines of the heart and aorta, have in many instances served to establish an entirely different diagnosis, namely, that of esophageal disease.

Diseases of the Stomach and Duodenum.—Since gastric acidity decreases with advancing age, it was the general belief about 30 years ago that ulcers of the stomach and duodenum would, therefore, disappear or become quiescent. The situation is different today and it is now recognized that either acute or reactivated ulcerative disease of the stomach and duodenum is relatively common in patients more than 60 years of age. In his afore-mentioned studies, Monroe found that 6.4 per cent of the more than 8,000 admissions to the Geriatric Clinic were for peptic ulcer; in only about half these cases was the usual long and classic history obtained. In one home operated by the Veterans Administration, 60 per cent of all gastrointestinal admissions from the home to the hospital are because of ulcer problems involving obstruction, bleeding or penetration and almost universally requiring surgical consultation and study.

Some interesting points are found with regard to the location of peptic ulcers in older patients. In the population as a whole there are probably ten duodenal ulcers to every gastric ulcer. In the aged, this ratio falls to about 3.5:1. Some correlation may exist between gastric ulcer and degenerative arterial disease, which may be of clinical importance, especially in connection with the cause of gastric ulcers and the seriousness of bleeding from them.

The patient with a long-standing ulcer history who experiences reactivation of his ulcer diathesis in later years presents no particular problem. There is a sizable group of old patients, however, who present their first ulcer symptoms in the seventh decade of life. In such patients bizarre symptoms appear to be the rule rather than the exeception.

The usual sequence of pain with an empty stomach and ease with food often does not appear, being replaced by symptoms having little relationship to those usually described by ulcer patients. A common story is that of isolated attacks of severe pain unrelieved by anything short of narcotics and not infrequently associated with vomiting and bleeding. Other patients may complain of pain aggravated by the taking of food or of periodic vomiting.

Complications, as already indicated, are almost the rule in the aged. Of these the most serious is bleeding, which not infrequently comes out of a clear sky. Duodenal ulcers apparently bleed a little less often than do ulcers on the gastric side. Men have more hemorrhages than women. Both the incidence and gravity of hemorrhage appear to increase with age, with a corresponding effect upon mortality. The true incidence of hemorrhage is difficult to determine, figures of from 5 to 30 per cent appearing in the literature; in Monroe's series, the latter percentage obtained. It is difficult to estimate the severity of hemorrhage in the aged, and a high incidence of cardiac and cerebral thrombosis follows hemorrhage, even that of moderate degree.

Obstruction is noted in about 10 to 15 per cent of old patients with ulcer, slightly more often with gastric than with duodenal lesions. Many of these patients have symptoms and roentgenologic findings suggestive of cancer. Obstruction may appear suddenly and with little in the way of antecedent history. Persons who have acute obstruction are a particular problem and may need hospital study with repeated checks of gastric retention and radiologic studies before a final diagnosis can be made. It should be pointed out that imbalance of electrolytes and azotemia develop with extreme rapidity in older patients after either hemorrhage or obstruction and that neglect of fluid balance for as little as a day or so may result in serious complications. Most of these older patients with pyloric obstruction can be handled well by simple surgical procedures, such as gastroenterostomy with or without excision of the ulcer. Fortunately, perforation occurs only about half as often as obstruction. A pronounced sex difference is noted, perforation being five times as common in men as in women.

What impresses gastroenterologists in dealing with the older ulcer patient is the bizarre symptomatology, the high incidence of complications and the relatively high mortality and morbidity rates; the persistence of the ulcer diathesis beyond the seventh decade of life is also impressive. Obviously, we should make roentgenologic studies of the stomach on more old patients even if the history is bizarre; we must be particularly quick to investigate a history of gastrointestinal bleeding, even if the amounts of blood lost are small. Finally, if the patient is seen for the first time with hemorrhage or other complications which might be attributed to ulcer, immediate investigation is compulsory.

One final point is stressed by gastroenterologists who have dealt extensively with ulcer in older patients. Treatment should never be continued for any length of time on the basis of symptomatology alone without confirmatory roentgenologic studies. Even after examination has revealed a lesion that appears to explain the complaint, and even if symptoms are benefited by medical management, further roentgenologic studies after a lapse of time are necessary. The high incidence of neoplastic disease in the stomach should warn us not to be misled by a solitary roentgenogram that shows a supposedly benign lesion.

Diseases of the Gallbladder.—Thirty years ago, when disease of the gallbladder was suspected in all middle-aged patients who had any sort of dyspepsia, a good many unnecessary cholecystectomies were done. Over the years the pendulum has swung in the opposite direction and today even cholecystography is often omitted unless the patient has had fairly classic symptoms referable to the biliary tract. As a result, a great many persons are going into the later years of life carrying gallstones which are not suspected until a catastrophe of some sort occurs.

The increasing incidence of gallstones with age requires only brief mention. Women apparently form most of their gallstones between their middle twenties and the menopause. In men the process starts later and continues into the eighth and ninth decades of life. The end result is that the incidence of stones in the two sexes becomes nearly equal in the very old. Many of these stones remain completely asymptomatic for life; others produce their first and only symptoms in advanced age. It is well to remember that gallstones are probably the commonest single cause of serious abdominal pain in patients more than 65 years of age and that neither the location nor the exact character of the pain is of much diagnostic value.

Should the accidentally discovered calculous gallbladder be removed in older patients? Is a single bout of pain sufficient indication for radical treatment? These questions are practical and the answer is not always simple. When statistically considered, the answer must be in the affirmative.

If one checks present hospital mortality rates from gallstones against the generally accepted surgical risk, it will be found that the mortality rate of stones in older patient is much higher than the least optimistic figures on surgical risk. In old patients the complications of gallstones and associated disease are jointly responsible. In Monroe's series there were many patients with cholecystenteric fistulas, gallstone ileus, common-duct stones and obstructive cirrhosis, to say nothing of associated pancreatitis; in the same series, the incidence of vascular complications was high. About 44 per cent of the patients who had gallstones had associated nonvalvular heart disease and 10 per cent had had previous cerebrovascular accidents.

Thus, gallstones are a distinct hazard to life which increases rapidly with age. Surgical mortality rates run a parallel course, although as a rule the old patient with gallstones stands operation well and there are few contraindications. The mortality rate of all patients with gallstones, according to Monroe, is materially increased above the hospital mortality rate of all old patients by at least 10 per cent. In his series, 4.5 per cent of the "medically treated" patients with gallstones died in the hospital solely as a consequence of their biliary disease and 8.5 per cent died from gallstones with complicating disease elsewhere in the body.

Diseases of the Small Intestine.—Regional ileitis is rare at all ages and decidedly uncommon among the old. The disease appears to present no special features in the later years of life. Whether healed ulcerative or granulomatous disease in early years leaves any residues that persist into the later years of life is not known. I recall three instances of intestinal strictures from my own experience; one caused obstructive symptoms of some severity while the others caused difficulty of a relatively mild degree. In two the origin was unknown; the third was associated with polyarteritis.

Diverticula in the small intestine, not uncommon in the aged, interest the radiologist but are rarely productive of serious symptoms. Duodenal diverticula in particular are probably of no great clinical importance, although a few are known to have produced mechanical difficulties chiefly because of their large size. Meckel's diverticula are rarely considered in diagnosis, yet I know of a recent case in which one produced obstruction in a 92-year-old man. This lesion was successfully resected and the obstruction relieved.

Diseases of the Colon.—If one arbitrarily excludes cancer from the discussion, only a few organic conditions involving the colon remain to be considered in the older age group. Ulcerative colitis is rare in geriatrics, yet an occasional case is found even in the aged.

One sees on histories a great many diagnoses of diverticulitis of the colon. Diverticula themselves are as common after 50 years of age as gray hair or wrinkles; they rarely produce symptoms until they are called to the patient's attention. In private practice a really significant attack of diverticulitis is something of a rarity.

One sees frequently on radiologic examination of older persons a narrowed cicatricial strip of intestine beginning in the descending colon and extending into the sigmoid. These lesions are probably truly the consequences of previous diverticulitis. They may simulate cancer, although their length and the rather indefinite terminal margins they present argue against such a diagnosis. In a few patients, cicatricial obstruction of the region may occur which can be relieved only by surgical excision of the diseased segment of intestine. It has been said that lesions of this type do not bleed, yet I am sure that some must do so. One woman, aged 83, with this radiologic picture bled from the intestine for years in quantities such as to require frequent transfusions. In spite of many roentgenologic studies and two laparotomies, no other cause for the bleeding point was ever found.

Much has been said and written about polyps in the colon. The small multiple polyps so frequently seen during sigmoidoscopy are easily fulgurated and removed. Larger single, adenomatous polyps, which produce symptoms by mechanical blockage of the intestine or by ulceration and hemorrhage, are not uncommon in older patients. Since many of them are potentially malignant, their removal must be advised, but in my experience the expected cure of the vague abdominal complaints so commonly associated with them does not materialize.

Some special mention must be made of appendicitis in the aged. Dr. Egeberg has commented on the frequency of appendiceal rupture in old patients associated with only moderate inflammatory reaction. These ruptures are apparently caused by distal obstruction incidental to cancer, the cicatricial residues of diverticulitis, volvulus or perhaps even constipation. There is no more difficult diagnosis than that of appendicitis in an old person. The symptoms are bizarre and the peritoneal reaction minimal; suspicion frequently is the only possible basis for diagnosis. All too frequently a diagnosis is not suspected until an abscess develops.

The major problem referable to the colon in old patients is constipation. No bulk formers, lubricants or antispasmodics will get much of a performance out of the old colon. What one should attempt to do is persuade the patient that the intestine need not be emptied every day and that no physical harm will result from an overdue stool. Such arguments leave most old people unmoved, and it is a rare person who has not worked out his own salvation by means of various laxatives, suppositories or enemas. It takes a hardy physician to attempt to correct some of these notions and no amount of talking can divert some oldsters from their preoccupation with their bowel habits.

The diarrheas of old people are troublesome. In some instances, they are associated with achlorhydria and probably also with deficient intestinal absorptive capacity. Such difficulty may be relieved in part by parenteral administration of liver extract and use of vitamin concentrates. Orally administered antibiotics may be responsible for setting the stage in many such patients. In others, no apparent explanation is available and one has little to offer except purely symptomatic measures. The nature of such diarrheas is obscure; much further study of the subject is needed.

Hepatic and Pancreatic Disease.—Cirrhosis of the liver does not frequently present itself as a clinical problem in the later years of life. This is probably due to the fact that the peak incidence of cirrhosis as a cause of death is past at age 60. Also, many types of cirrhosis are inconsistent with long life. Hemochromatosis and biliary cirrhosis (often described as xanthomatous) usually have run their course long before the seventh decade. Somewhat the same statement may be made in regard to chronic hepatic atrophy, an especially lethal ailment in postmenopausal women. What remains, therefore, is chiefly nutritional cirrhosis and the cause is, in most instances, alcohol plus malnutrition. The incidence of the disease varies with the location and dietary habits of the community.

As might be expected, the complications of cirrhosis, chiefly hemorrhage from varices and episodes of hepatic necrosis, are highly fatal in old persons. Some fortunate patients, however, appear to achieve a balance between cellular destruction and repair, with the result that the aged patient may carry on successfully. I recall a number of older patients with cirrhosis who presented every evidence of gross hepatic damage and yet survived for years in a reasonable state of health. One man to whom a fatal prognosis was given at the time of his admission to the hospital lived for 10 years, dying of arteriosclerosis. One should not despair of the older cirrhotic; he deserves as vigorous treatment as the younger patient and not infrequently will reward these efforts by a long and reasonably comfortable life.

Viral hepatitis is no respecter of age. Epidemiologic study appears to indicate that persons in middle life and beyond have a fairly solid immunity to the naturally acquired disease but this conveys no immunity to the serum-borne type. Probably because of this fact and the likelihood that hepatitis in the aged may be due to virus SH, by far the more dangerous type, the prognosis in the old patient with hepatitis should be guarded. The state of the patient's nutrition and the presence or absence of associated disease elsewhere in the body may be determining factors in the outcome. It is wise to study the old person with jaundice with great care, since the difficulty of diagnosis between obstructive and parenchymatous jaundice apparently increases with age. The patient who has a definitely obstructed biliary tree cannot be explored too promptly, whereas the patient with primary hepatic cellular disease must be kept out of the operating room.

Chronic relapsing pancreatitis appears to be relatively rare in older persons but it does occur often enough to keep one constantly reminded of its presence. Pancreatic edema associated with common-duct stone is, of course, frequently seen and is relieved when the offending calculus is removed. Two patients recently seen with episodes of hemorrhagic pancreatic necrosis were in the seventh and eighth decades of life. Both recovered after a long and stormy illness characterized by imbalance of electrolytes and azotemia. It is encouraging to be able to tell these patients that only about half of those who have this syndrome will have a recurrence. Surgery in such patients is probably better avoided, but one must make an exception for the patient with a pancreatic cyst. The suspicion of cancer is ever present in this group of individuals but it appears well established that the more violent episodes of illness are most often associated with the benign form of pancreatic disease.

Functional Complaints of the Aged.—These are legion even in persons who have an underlying organic disorder. In these patients one has to pick up the trail of an organic disorder out of the maze of bizarre symptoms. One must beware of the alleged functional complaint in patients more than 45 years of age; this statement is doubly true for patients more than 60 years of age. One learns to be cautious in commitments made to these patients and to advise re-examination if the character of the symptoms changes.

There are, however, innumerable older persons who always have had digestive disturbances that simply grow in number and magnitude with the passing of years. Among these, certain types stand out, such as the bolters of food and the swallowers of air, who usually can be distinguished by their ability to belch at any time and as frequently as desired; another type is the confused oldster who has himself imagined or has been led to believe that he has food allergies or sensitivities and who as a result has restricted his diet severely. To convince these people of the error of their ways and to get them back on a full and proper diet require diplomatic skill of the highest order. A third group, and perhaps the commonest of all, are persons with so-called mucous colitis. It is a fortunate physician who does not have a group of these unfortunate patients under his care. To the best of my knowledge there is no dietetic program nor any combination of drugs which will restore peristaltic activity to normal in the colons of these individuals. With persuasion and guidance, some of them improve, but more often they drift disconsolately from one physician to the next, obtaining little relief from any.

Finally, some comment must be made about the organic psychoses of old age and their tendency to produce digestive symptoms. Minor cerebrovascular accidents, encephalomalacia of arteriosclerotic origin and even simple reactive depression may produce somatic digestive symptoms of a most bizarre type. The depressive episode may pass and the digestive complaints disappear, but with organic cerebral damage, prognosis for recovery is not good. If any help is to be obtained for these older persons with functional digestive complaints, it is usually at the hands of the wise family physician who knows

(Continued on Page 330)

Management of Acute Abdominal Diseases

WILLIAM H. ReMINE, M.D.
Rochester, Minnesota

THE diagnosis and management of acute diseases of the abdomen continue to be among the most perplexing problems that confront the surgeon today. Regardless of the tremendous strides in modern medicine, considerable room for improvement exists in this field. It must be remembered that the first successful closure of a perforated peptic ulcer was done less than 50 years ago and that removal of a diseased appendix has been a practical surgical procedure only for about the same time. Laparotomy for intestinal obstruction was regarded until comparatively recently as a procedure of last resort.

Needless to say, the most important and also one of the most difficult problems is that of arriving at the correct diagnosis. While it is not within the scope of this paper to discuss the taking of a history and the performance of the physical examination, it should be emphasized that extreme care is needed at this crucial stage. Among the several diseases that simulate an acute surgical condition of the abdomen are cardiac derangements, chronic interstitial nephritis, pneumonia, porphyria, hydronephrosis, typhoid fever, tuberculous peritonitis and tabes dorsalis. The latter three diseases are not seen nearly so often as formerly. For some time it has been the policy of my surgical colleagues and me to require as routine on all candidates for emergency surgical treatment a certain minimum of laboratory studies, including a complete blood count, urinalysis, thoracic roentgenogram, a scout (preliminary survey) film of the abdomen when indicated, and determination of the blood group and Rh factor. Other studies may be done depending on the particular problem at hand; these include such things as roentgenograms of the abdomen with the patient upright or in the lateral decubitus position to determine the presence of free air, and chemical determination of values for serum amylase and lipase. Such studies are of considerable value when used in the proper situation, but they should not be ordered indiscriminately as they are time-consuming and expensive.

Stomach and Duodenum

Acute hemorrhagic peptic ulceration, either gastric or duodenal, is a most formidable problem. Constant observation of the pulse, blood pressure and value for hemoglobin is necessary in addition to the usual administration of blood and other supportive fluids. Massive bleeding must be brought under control without delay. The patient who has such hemorrhage presents a considerably different problem than does the usual type of bleeder. The mere induction of anesthesia may prove fatal as a result of aspiration of large quantities of regurgitated blood. During the past two years my surgical colleagues and I have worked in close co-operation with the anesthesiologists and have established a routine method of management in these difficult situations. Since its inception, the surgical mortality rate has been greatly reduced.

Our present method of surgical management of bleeding peptic ulcer is as follows: two 15-gauge needles are inserted into the veins even if it is necessary to cut down on the veins to accomplish this. It is thought that complete and adequate control of two veins is of utmost importance in the maintenance of an adequate circulating blood volume. The systolic blood pressure should be maintained at more than 80 millimeters of mercury in order to be well above the minimal pressure for renal filtration and thereby forestall development of lower nephron nephrosis. The abdomen is opened after local infiltration with procaine has been accomplished. The stomach will be greatly distended and filled with blood and clots; therefore, the stomach is opened and evacuated immediately so that the patient can-

The Mayo Foundation, Rochester, Minnesota, is a part of the Graduate School of the University of Minnesota.

not regurgitate large quantities of blood. The anesthesiologist then puts the patient to sleep and inserts an intratracheal cuffed tube. Thus, with complete control of both the circulatory system and the airway, the surgeon can proceed with the operation with relative ease and considerably less risk to the patient.

The next problem is to bring the bleeding point under control by either suture or ligature; once this is accomplished, the condition of the patient will become stabilized fairly well. Of course, blood is being replaced all the time, and after the bleeding has been stopped the surgeon can proceed with an adequate and satisfactory gastric resection of whatever type is preferred.

Perforated peptic ulcers have had considerable attention recently due to the advocacy of conservative methods of management by some workers. For the most part, my colleagues and I continue to treat perforated ulcers surgically. At present no attempt is made to close a perforated gastric ulcer, since it cannot be determined immediately whether such a lesion is an ulcer or a carcinoma. Therefore, these lesions should be resected whenever possible.

Perforated duodenal ulcer presents a somewhat different problem. The diagnosis of an acute perforated duodenal ulcer is made from the criteria of previous ulcer history, sudden onset of acute abdominal distress, free air in the abdomen and an increased value for serum amylase. The serum amylase is increased usually to 500 or 1,000 units in perforated duodenal ulcer; this finding is often important in differentiating this disease from acute pancreatitis, in which the value for serum amylase is considerably higher, often ranging from 3,000 to 4,000 units. As soon as the diagnosis of perforated peptic ulcer is made, the patient should be prepared for operation unless very definite localizing signs are demonstrable.

Such preparation consists of immediate gastric intubation to rid the stomach of its contents and prevent further leakage into the abdomen. In addition to this, the patient receives parenterally large doses of atropine or methantheline bromide (banthine) to further inhibit gastric secretion and also to inhibit pancreatic secretion. The patient should receive large doses of antibiotics, with morphine or some similar narcotic to allay the pain; intravenous administration of fluid or blood tranfusions are given as necessary to treat shock or to restore proper hydration. The perforation is then promptly closed.

Many times the abdominal cavity will be greatly soiled with contents from the stomach and duodenum, and severe chemical peritonitis will be present as a result of the gastric acid, bile and pancreatic juice liberated into the peritoneal cavity. Under such conditions, the peritoneal cavity should be lavaged profusely with large quantities of saline to remove such material and reduce the extent of chemical peritonitis. A mixture of penicillin and dihydrostreptomycin is left in the abdomen to combat the growth of any bacteria that might have been introduced into the cavity. As the result of use of this method, there have been no deaths at the Mayo Clinic in the last two years from perforated peptic ulcer.

In addition to this regimen, more perforated duodenal ulcers are now being resected than before. Many patients who have had simple closure of a perforated duodenal ulcer will return later because of reperforation, obstruction or hemorrhage. If primary resection will spare the patient a second major surgical procedure, the surgeon probably is obligated to do this whenever possible. However, primary resection should not be used indiscriminately, and candidates for the procedure should be picked with great care.

A number of factors enter into the selection of patients for primary resection of a perforated duodenal ulcer. The age of the patient should come into consideration, but no hard and fast rule can be set; a 65-year-old patient may be in unusually good condition for his age. The general condition of the patient is important; the physician must use his clinical judgment in evaluating the condition of each patient. The amount of soilage in the abdomen should be considered. If the patient is having a great amount of shock resulting from severe chemical peritonitis, the surgeon should not add to that shock by attempting a long procedure, such as gastric resection. The duration of the perforation is also to be considered. If the perforation has been present for some time, much contamination has occurred and the patient's condition may not be good; under such conditions, mere closure of the ulcer should be done. The condition of the duodenum is of prime importance. This will determine whether or not adequate closure of the duodenal stump can be done. If the tissues are in poor condition, friable, or edematous, if much fore-shortening is present, or if the perforation is extremely large and occupies a major portion of the wall of the anterior surface of the duodenum, then it is not wise to attempt resection and run the risk of a draining duodenal stump in addition to the many other associated problems.

Gallbladder

Difference of opinion continues as to when operation should be performed in acute disease of the gallbladder. Patients with this disease must be carefully individualized. Emergency surgical intervention does not have to be considered for patients who are merely having minor attacks. Patients having attacks severe enough to necessitate admission to a hospital or repeated injection of narcotics for relief of pain present a considerably different problem. Such patients may be evaluated on the basis of several factors, among the most important of which are (1) the duration of the present attack, (2) the severity of the present attack, (3) the number of previous attacks and (4) the association of pancreatitis.

If the duration of the present attack has been as short as twenty-four hours or so, it is advisable to observe the patient for a while longer, perhaps an additional twelve to twenty-four hours. This allows time to show improvement, and in the meantime proper medical management can be instituted. At the end of this period if the pain and other symptoms are less and the temperature is on the decline, then the program should be continued. If, however, the condition of the patient has not improved or has become worse, then surgical intervention is indicated. At the end of this period, the attack has not been of sufficient duration for the surgical procedure to be technically difficult because of inflammatory reaction. On the other hand, if the attack has lasted five or six days, the affected tissue by this time has become so brawny and ligneous that cholecystectomy is extremely hazardous and difficult and should not be attempted if it can possibly be avoided. Thus a duration of five or six days is the upper margin of safety beyond which operation is not recommended until after the attack has subsided.

The number of previous attacks may play an important role in determining the best form of treatment for a particular patient. If the patient is seen in a severe attack and has not had previous gallbladder disease, that patient should be operated on immediately. It is largely among this group that free perforation of the gallbladder is found, associated with bile peritonitis. This is due primarily to the fact that the adjacent abdominal structures have not yet had an opportunity through repeated minor attacks and resultant inflammation to wall off the area around the gallbladder and thus prevent so-called free perforation. Approximately 4 per cent of all acutely inflamed gallbladders will perforate.

In the event of associated pancreatitis, which is evidenced by pain penetrating through to the back and by an increase of serum amylase, surgical intervention should be postponed if at all possible. This is especially true since these patients may have a stone in the common bile duct, which would necessitate exploration of the duct. This is technically difficult in the presence of severe inflammation; therefore, operation should be delayed if at all possible until after the attack has subsided sufficiently to allow the inflammation to subside, which usually takes two or three weeks after onset of the disease.

Pancreas

Acute pancreatitis continues to be a most difficult and often lethal problem. A rigid abdomen, a shocklike picture and greatly increased values for serum amylase and lipase, in the absence of free air in the abdomen, lead to the diagnosis of acute pancreatitis. In the past, several procedures have been offered for use in surgical management of this disease. Among these are drainage of the common bile duct, drainage of the region around the pancreas and splitting of the capsule of the pancreas. These methods have not proved to be of sufficient value to recommend their routine use. Instead, a properly managed conservative regimen appears to offer considerably more than does surgical intervention in this disease and does not add to the already existing shock of the patient.

As soon as the diagnosis of pancreatitis is made, all efforts should be directed toward the suppression of pancreatic function, general support of the patient and the relief of pain. The patient should receive nothing by mouth and continuous gastric suction should be instituted. This removes the gastric acid as a source of pancreatic stimulation. Use of morphine and codeine should be avoided as these drugs frequently may cause spasm of the sphincter of Oddi, thus hindering pancreatic drainage. Other drugs for the relief of pain should be used, however, in sufficient doses to give adequate relief. Large doses of atropine or banthine given parenterally should be used to suppress gastric as well as pancreatic function. Massive doses of broad-spectrum antibiotics should be given, as sterile abscesses frequently form from necrosis of tissue and pancreatic digestion and these may be secondarily infected by bacterial invaders. Adequate amounts of fluid and blood should be given parenterally as indicated. This program has proved to be satisfactory and has greatly reduced mortality rates in the management of this disease.

Small Intestine

Emergency problems of the small intestine may be divided into three main groups, namely (1) those related to Meckel's diverticulum, (2) those resulting from mesenteric vascular occlusion as the result of either thrombosis or embolism and (3) obstruction from such conditions as adhesions, congenital bands, volvulus, tumors (either benign or malignant, such as polyps, lipomas, myomas, adenocarcinomas and carcinoids), and foreign bodies, such as ingested articles and gallstones.

Meckel's diverticulum may give symptoms from bleeding, obstruction or perforation. The diagnosis usually is made by exclusion, as there are no good pathognomonic signs to indicate the lesion.

Mesenteric thrombosis may be acute or insidious in onset depending on the causative situation. The existence of ventricular fibrillation often may give a clue but this is not necessarily a prerequisite for mesenteric vascular occlusion. Venous thrombosis may be a more frequent cause of mesenteric vascular occlusion than is arterial embolism; the former may occur on the basis of cardiac failure with resultant decompensation and diminished venous return. The affected tissue must be resected; otherwise the outlook is extremely poor.

The diagnosis of intestinal obstruction may be made on the following criteria: intermittent crampy pain, borborygmi at the height of the pain, nausea, vomiting, interference with bowel movements, abdominal distention, localized abdominal tenderness and roentgenologic evidence. Certain factors contribute to a late diagnosis in acute intestinal obstruction. These include failure to recognize intestinal colic, failure to auscultate the abdomen, frequent lack of local findings, confidence in enemas, apparent effect of laxatives and premature use of morphine.

Whenever possible it is always well initially to try conservative methods in the management of simple intestinal obstruction. Such methods include giving nothing by mouth, intestinal intubation, parenteral administration of fluids, hot abdominal stupes, inhalation of oxygen, blood transfusion when necessary, warm gentle rectal irrigation and close observation, including blood chemical determinations and roentgenograms of the abdomen.

Obstruction of the small intestine presents many varied problems. Adhesions and congenital bands are the cause in the great majority of cases. In the case of adhesions, medical decompression by means of a Miller-Abbott tube or some other type of long intubation tube, if possible, is preferable to surgical procedures because the latter only produce more adhesions.

Volvulus of the small intestine presents an extremely serious problem. Often an indication to the correct diagnosis may be noted on a scout film of the abdomen. A characteristic roentgenologic picture is the so-called almond-shaped deformity, which is pathognomonic of a closed-loop obstruction of the small intestine, or so-called volvulus. Once this picture is seen, the patient should be operated on immediately; otherwise gangrene of the intestinal loop will develop, necessitating a much more extensive procedure, with resection of a segment of the small intestine.

Tumors that produce obstruction must be removed surgically. It is best, however, to decompress the intestine as much as possible beforehand, as this will make the operative procedure considerably easier for both the surgeon and patient. Resection of the small intestine may be unusually dangerous, especially when one is forced to attempt anastomosis in a distended edematous friable segment. In order to put the tube into the small intestine as far down and as rapidly as possible, it is often necessary to push the tube into the small intestine through the pylorus with the aid of fluoroscopic examination. Tubal decompression may greatly improve the integrity of the tissues with which the surgeon is forced to work.

Foreign bodies occasionally may cause intestinal obstruction; many of them can be noted on a scout film of the abdomen. Ileus produced by a gallstone, however, is an extremely difficult problem to diagnose preoperatively at times, yet to the careful observer the diagnosis frequently may be made from the scout film. The stone itself seldom may be seen; however, the presence of free air in the biliary tree is pathognomonic of gallstone ileus. This finding means that the patient should be operated on immediately, because it is indicative of air that has escaped into the biliary tree through the fistula between the gallbladder or the common bile duct and the small intestine. The stone usually will lodge in the distal 5 or 6 cm. of the ileum, with a marked amount of inflammatory reaction around it and a considerable degree of distention above it. When the stone is found it should be milked proximad away from the inflamed and edematous intestine up to a normal segment, where a small incision can be made through the wall of the intestine, the stone removed and the incision closed with minimal difficulty. One per cent of all obstructions of the small intestine are due to gallstones.

Large Intestine

Acute emergencies involving the large intestine may be generally divided into three main groups, namely (1) those resulting from appendicitis, (2) those resulting from diverticulitis and (3) those resulting from obstruction from other causes. Appendicitis will not be considered in this presentation because relatively little recent change has occurred in the management of this disease.

Diverticulitis is primarily a disease of middle and old age. Five to 10 per cent of persons more than forty years of age have but do not suffer from diverticulosis. Of these persons, one in 300 experiences diverticulitis. Diverticulosis is twice as common among males as among females but diverticulitis has an equal sex incidence. Diverticulitis is located in the sigmoid in 75 per cent of cases. Emergency surgical procedures for this condition are indicated only in the presence of free perforation or obstruction. A transverse loop colostomy to divert the fecal stream is usually all that should be done initially, and more definitive surgical treatment should be planned for a later date. Rarely the affected region may be exteriorized. Primary resection of the perforated obstructed segment is difficult because of the severe inflammatory reaction and seldom can be accomplished. Other conditions of the colon that necessitate emergency surgical procedures are volvulus and closed-loop obstruction.

Carcinoma of the sigmoid and rectosigmoid appears to be the commonest cause of closed-loop obstruction in the presence of a competent ileocecal valve. A closed-loop obstruction may be readily recognized on a scout film of the abdomen by the severe distention of the colon, with apparent absence of gas in the small intestine. These patients should be followed with extreme care since perforation of the cecum may be imminent. Impending cecal perforation may be diagnosed by the following criteria: progressive cecal enlargement as evidenced by roentgenologic studies, pain and tenderness over the cecal region, rebound tenderness over the cecal region and an increase in pulse rate. Many times in the presence of closed-loop obstruction, the first symptom may be pain in the right lower quadrant, which will draw attention away from a lesion in the sigmoid or rectosigmoid and may cause it to be overlooked. The reason for such pain with an obstructing lesion in the sigmoid or rectosigmoid is that the cecum is the thinnest and most easily distensible part of the intestine, which is why it also is the commonest point of perforation.

When the afore-mentioned findings are noted, immediate surgical decompression is compulsory. In our experience the procedure of choice in this instance is transverse loop colostomy. Some surgeons favor use of appendicostomy or cecostomy. It has been our experience that an appreciable number of the stomas established by these latter procedures do not function in a satisfactory manner and failure to function at this crucial time may prove fatal.

Thousands of people are abroad in the country with tuberculosis which is arrested or inactive following treatment. Antibiotics have played a large part; and we hope these people will remain well for many years, but how many will relapse, we do not know. How many may at some time produce tubercle bacilli, which may be a danger to the community, we do not know. Will the antibiotics lose their effectiveness as the number of resistant cases increases in the community? Again, we do not know. It is such uncertainties that lead the pessimists to say that tuberculosis, like the poor, will be always with us.—George J. Wherrett, M.D., National Tuberculosis Association Transactions, 1954.

Hematuria

JOHN L. EMMETT, M.D.
Rochester, Minnesota

MODERN physicians are fully aware of the potential seriousness of hematuria and advise patients who have such a condition to undergo prompt and thorough examination. The tragedies that occur from delayed diagnosis of malignant lesions of the genitourinary tract often can be ascribed to the patient, who either does not seek advice immediately after hematuria appears or ignores the counsel of his physician. The public must be educated to the seriousness of hematuria.

Hematuria always demands a qualifying adjective, namely either gross or microscopic. Gross hematuria always means an abnormal or pathologic situation. On the other hand, the finding of microscopic hematuria always brings up the unanswered question with regard to whether or not a few erythrocytes may be present in the urine of normal persons. The bulk of evidence accumulated over the years would indicate that, with ordinary techniques of urinalysis, the presence of more than two erythrocytes per high-power microscopic field in a centrifuged specimen is abnormal. Of course, many variables enter into this conclusion, such as the accuracy of the technician, the speed of the centrifuge and the specific gravity of the urine. Dilute urine contains fewer erythrocytes than does an equal volume of concentrated urine.

Sites of Origin of Hematuria

There are three main possible sites of origin of hematuria, namely lesions occurring as part of a systemic disease, lesions in organs adjacent to the genitourinary tract and lesions in the genitourinary tract itself. Among the systemic diseases that may cause erythrocytes to appear in the urine are (1) acute or chronic nephritis; (2) diseases of the blood-forming organs, such as thrombocytopenic purpura, leukemia, Hodgkin's disease, hemophilia and polycythemia vera; (3) cardiac disease, as in congestive cardiac failure or renal infarction resulting from rheumatic carditis and auricular fibrillation; (4) acute exanthematous diseases and (5) deficiency diseases, such as deficiency of ascorbic acid or vitamin K. Drugs and chemicals, such as methenamine, carbolic acid, turpentine and sulfonamides, may produce hematuria, as may administration of anticoagulants, such as dicumarol or heparin.

Lesions in organs adjacent to the urinary tract can be disposed of briefly by simply stating that the possibilities are unlimited. Among such lesions that may produce hematuria by irritation or invasion of the genitourinary tract are appendicitis, salpingitis, diverticulitis and carcinoma of the colon.

The remainder of this presentation will be devoted to a consideration of lesions of the genitourinary tract itself.

Microscopic Versus Gross Hematuria

The presence of asymptomatic microscopic hematuria is perhaps more troublesome to the physician than is gross hematuria because it is encountered more frequently and is associated with a much smaller incidence of serious disease; yet the physician does not dare neglect such a finding. Significant lesions will be found in approximately 5 per cent of such cases; thus the clinician would like the urologist to furnish a rapid and simple screening procedure that would eliminate the 95 per cent of cases in which such minimal hematuria is insignificant. To date such a procedure is not available and it is necessary to subject 100 patients to such procedures as excretory urography, cystoscopy and retrograde pyelography to discover the five or six who have significant lesions. In some of the cases in which no lesions are discovered to explain the hematuria, the condition simply may be normal erythrocyturia. In some cases hematuria may originate from trauma as a result of digital rectal or pelvic examination

before the urine was obtained. In other cases, subclinical nephritis or a small angioma of the kidney may be present. It is apparent that asymptomatic microscopic hematuria is a worrisome problem whose solution is not always satisfactory.

Gross hematuria is a less troublesome problem, at least to the physician, simply because it is associated with such a high incidence of significant and serious lesions that a complete urologic examination is compulsory.

The commonest cause of gross hematuria in a woman is inflammation, usually cystitis or pyelonephritis. The commonest cause of gross hematuria in a man is a tumor of the bladder, with hypertrophy of the prostate in second place. An important point to emphasize is that benign enlargement of the prostate causes hematuria much more frequently than does carcinoma of the prostate.

General Clinical Aspects of Hematuria

When the physician is confronted with a patient who has gross hematuria he first considers the age of the patient. Hematuria is rare in infancy and childhood; usually it is the result of infection in such instances. Such infections usually are produced by stasis, which usually is caused by congenital obstruction. The latter is ordinarily at one of three chief points, namely the ureteropelvic juncture, the vesical neck or, in the male, the urethral meatus. Tumors of the genitourinary tract in infancy are rare and are chiefly Wilms' tumors and sarcomas. Such lesions rarely cause hematuria; they are diagnosed because they present themselves as abdominal masses.

With regard to gross hematuria in adults up to 40 years of age, the common causes include infection, cystitis, pyelonephritis, tuberculosis and calculi. Tumors are relatively uncommon in this age group. However, in patients more than 40 years of age, the incidence of neoplasms and prostatic lesions, both benign and malignant, becomes increasingly common.

The type of hematuria may give some clue as to its origin. Initial and terminal hematuria usually is considered to indicate a lesion in the neck of the bladder or the prostatic portion of the urethra. If it is present in the same degree throughout urination and if the blood is dark, the lesion is thought to be in the upper part of the urinary tract, whereas if the blood is fresh and bright, it supposedly comes from the bladder. However, it is not wise to place too much reliance on this finding. Blood that emerges directly from the urethra and soils the clothes of either a man or a woman originates distad to the external sphincter. It is well to be cautious about a story of bleeding in a woman. The physician must take a careful history and be extremely patient with a woman in order to ascertain whether she is talking about vaginal bleeding, about urethral bleeding or about cystitis; this is because of embarrassment and because many women do not understand the terms used. Sometimes a complete urologic and gynecologic examination is required to uncover the true situation.

The general physical examination may not be too productive in the diagnosis of hematuria but it should not be overlooked. Palpable renal enlargement may indicate neoplasm, hydronephrosis or a cyst of the kidney. Tenderness in the flank may indicate a stone, infection or hydronephrosis. Enlargement of a supraclavicular lymph node may herald hypernephroma. Acute left varicocele in a man past 40 years of age often means a left hypernephroma with invasion of the left renal vein, because the spermatic vein empties into the left renal vein. Digital rectal examination, which is so important, can aid in the diagnosis of carcinoma of the prostate, benign hypertrophy of the prostate or prostatic calculi. Vaginal examination may reveal infiltration at the base of the bladder from a tumor.

Excretory Urography

Emphasis should be placed on the value of excretory urography, including the plain roentgenogram of the kidney-ureter-bladder region that accompanies this procedure. This examination is of great importance in the diagnosis of urologic lesions because it is one of the greatest tests of renal function, indicating the comparative function of the two kidneys. The other factor of importance with regard to excretory urography is that it focuses attention on the part of the urinary tract that is involved, which is of great aid in cystoscopy.

Excretory urography can be of assistance in the localization of urinary obstruction, demonstrating whether such obstruction may be at the ureteropelvic junction or lower in the urinary tract. It can accurately localize calculi in the kidneys, pelves or ureters. It may demonstrate filling defects at the base of the bladder as the result of prostatic hypertrophy. Other filling defects may indicate infiltrating tumors of the bladder. Pedunculated tumors of the bladder may be outlined by the way in which the opaque medium surrounds them. Hypernephromas may be indicated by characteristic distortion of calyces. Tumors of the renal pelvis may produce typical filling defects.

Cystoscopy

It is usually necessary to perform cystoscopy to complete a urologic diagnosis because it is easier and more accurate to study lesions in the bladder under direct vision than to rely on urography entirely. Also, it is often necessary to do retrograde pyelography to supplement excretory urography. It is of importance to examine the patient urologically while bleeding is still present. So often a patient bleeds grossly for 2 or 3 days and by the time he gets ready for urologic examination the bleeding has stopped, making it difficult to determine the source of the hemorrhage.

Another element of importance in cystoscopy is to examine the ureteral orifices and watch the urine as it spurts from them. That is the only way to determine whether or not blood is coming from a kidney. Examination of a specimen of ureteral urine taken from a ureteral catheter will not necessarily indicate whether or not blood is coming from the kidney in question because the trauma caused by passage of a ureteral catheter in most cases will cause either microscopic or gross hematuria. However, the appearance of bloody urine flowing out from a ureter that has not been catheterized will localize the kidney that is bleeding.

In conclusion I wish to emphasize that the Bladder Tumor Registry indicates that 50 per cent of tumors of the bladder are not diagnosed within one year after the first attack of hematuria. This is a tragic situation; it means that all physicians must be on the alert in their practice and community to educate patients and the public to the seriousness of hematuria and the advisability of seeking medical advice immediately when it occurs.

CORTISONE IN RHEUMATIC DISEASES

(Continued from Page 308)

such treatment is indicated. Until better therapeutic measures are developed, cortisone and related hormones will continue to be important and valuable agents in the management of such patients.

Addendum

Since this paper was prepared, another potent antirheumatic steroid, namely metacortandracin, or 1-dehydrocortisone, has been synthesized. Although this steroid has less tendency than does cortisone to cause retention of sodium, chloride and water, and to produce excretion of potassium, it does cause many other cortisonelike metabolic effects. The dose of 1-dehydrocortisone (metacortandracin) necessary to produce an equivalent antirheumatic effect appears to be only a third or a fourth that of cortisone, perhaps even less in some cases. The use of this steroid should be attended by the precautions indicated during treatment with cortisone; however, restriction of intake of sodium and supplementation of potassium usually have not been required, at least not in rheumatoid patients treated for periods up to several months with doses of 5 to 20 mg. per day.

The Technique and Interpretation of the Vaginal Examination

EDWARD A. BANNER, M.D.
Rochester, Minnesota

MOST of us learn best by doing, and so it is fortunate indeed that the technique of the pelvic examination can be attained more by doing than by reading or hearing about it. What I have to say, therefore, is directed chiefly toward actual performance of this examination, with some attention to interpretation of what the examiner finds.

The conditions to which the physician's attention is called most often by women include inflammatory and infectious disease, new growths, sequelae of labor and endocrine dysfunctions which produce aberrations of menstrual function. Often the patient will seek your counsel because of abnormal vaginal secretions, genital bleeding or pelvic pain. Less often, she may come to you because of protruding masses or generalized pelvic or abdominal discomfort. Still others may visit your office because the persistent "cancer drives" have made them apprehensive, and they wish to reassure themselves by such routine measures of investigation as you are able to provide. Whatever the cause, it is certainly true that the number of such patients in the office of the gynecologist is increasing. The net result is to place greater responsibility on the physician, for if mass education sends more patients to him, he will be expected more and more often to detect malignant processes in earlier stages, where treatment can be swift and effective, and lives can be saved.

The Physical Examination

A general physical examination should follow the history and should, whenever it is possible, precede the pelvic examination.

What to Look For.—In the general examination of the patient much can be learned: her habitus, whether masculine or feminine, robust or frail, hirsute or balding—all may be noted with a glance. The temperature, pulse rate and blood pressure should be recorded. The breasts should be examined, for they are secondary sex characters and as such they share in many changes and physiologic conditions within the pelvis. In the abdominal examination the physician should note the presence or absence of striae indicative of rapid loss of weight, and evidence of past pregnancies or endocrine dysfunctions. Tender areas should be carefully palpated, and distinction should be made between rigidity and normal muscular defense reaction.

Much can be learned from an adequate abdominal examination, and although it is neglected by many, it may actually bring to the fore the primary difficulty at hand, especially if the patient is acutely ill or apprehensive. In passing, let us remember that a full bladder at times has deceived the shrewdest of examiners. For this reason, some gynecologists have suggested that the patient void immediately before examination to forestall such a diagnostic pitfall.

The Pelvic Examination

Whatever is learned after the history and the physical examination must be gained tactually, and must be correlated with information gained from those two procedures. The only way I know of to develop the tactile sense is to do enough pelvic examinations to acquire the faculty of instant recognition not only of the normal anatomic relationships but also the minor aberrations which are the hallmarks of pelvic disease. One should become familiar with the nodular tender areas involving the uterosacral ligaments and posterior uterine surface so characteristic of endometriosis; also the thickened, tender and bulbous swelling of the tubes portraying the aftermath of pelvic inflammatory disease.

Equipment.—All the necessary equipment for the proper performance of a pelvic examination should be at hand before the examination is begun. This would include drapes, hand protection, lubricants, light, material for taking smears, and a table which will offer the examiner every advantage.

Since the speculum is an indispensable instrument to the gynecologist, a word should be said regarding the various types available. For most purposes, the bivalve speculum is perfectly satisfactory. It is made in several sizes, and the examiner selects that size which can be introduced easily and does not cause discomfort to the patient. In children, the most satisfactory speculum is the tubular cystoscope, which is used with the patient in the knee-chest position. The tubular speculum likewise is available in a variety of sizes. For some patients the flat Sims speculum may be used to advantage. The physician should become familiar with the various speculums and their sizes to facilitate and insure maximal comfort to the patient.

Rapprochement With the Patient.—Establishing the patient's confidence is the greatest single factor in promoting ease of examination. Unconsidered remarks or chance actions which engender fear, resentment or anxiety may result in a tense, disturbed or apprehensive patient. Such a patient is rigid and ill at ease, and in a state that may make a pelvic examination impossible or seriously unproductive. In creating confidence, gentleness is the first essential. Relaxation may be encouraged by asking the patient to breathe through her mouth. Constant reassurance is helpful. No violation of modesty should enter the pelvic examination, but exposure should be consistent with thoroughness. The presence of a nurse or an assistant may aid in this respect, although it is not entirely necessary. Most of all, the physician should maintain an attitude of kindly and impersonal thoroughness. A pelvic examination is not a pleasant experience for any woman, and the success with which it is conducted will depend as much on the attitude of the physician and his assistant as upon the actual situation in the pelvic region.

What to Look For.—Inspection of the external genitalia is done with the patient in the lithotomy position, with the physician standing between the patient's knees. The vulva is inspected for dermal lesions, excessive secretions and tumor masses. Since vulvar neoplasms frequently metastasize to the inguinal glands, these glands should be palpated for tenderness or enlargement. Small, shotty inguinal glands are not unusual, especially in young women, and should cause no concern unless they are associated with definite lesions.

After examination of the vulva, the labia should be gently parted, and the size, shape and dermal changes, if present, should be noted carefully. Inspection for kraurosis vulvae, lichen sclerosus et atrophicus and leukoplakia should be made. If it is suspected that one such condition is present, the counsel of a dermatologist is of inestimable help in identification. If a discharge is present, the examiner should determine whether it is bloody, serosanguineous, purulent or mucoid. Normally, Bartholin's glands should not be palpable and Skene's glands should not be tender. If the hymen is intact, examination of the pelvic organs may be completed rectoabdominally. Careful note should be made of the caliber of introitus. By pressure exerted downward against the perineal body, more space may be obtained with less discomfort to the patient.

The condition of the pelvic floor is then determined. To determine the presence or absence of rectocele is not difficult, but may be rendered easier by pressure exerted upward on the posterior vaginal wall, through the rectum. The size, shape, consistency and position of the cervix should then be determined by palpation. A normal cervix is said to have the consistency of the end of the nose, whereas a cervix invaded by a malignant process generally has a hard or gritty consistency.

At this point, examination with the speculum is begun. It is well to recall at this point that the axis of the vagina is directed posteriorly, while the long axis of the introitus is anteroposterior. It is well, then, to introduce the speculum of the bivalve type with its long axis vertical, to conform to the shape of the vaginal orifice. This is preceded by separating the vulva and pressure on the perineal body. When it is well past the entrance of the vagina, the speculum is turned so that the blades lie transversely, with the tip of the speculum pointed posteriorly toward the vaginal floor when the blades are opened. The common practice of using soap or lubricants is not advisable, since soap alters the chemical reaction of the vaginal secretions and interferes with staining and cultural reactions. Lubricants also frequently make interpretation of Papanicolaou smears for malignant cells more difficult or even impossible. Rather, it is better to wet the gloved hand and speculum with warm water, thereby decreasing the shock to the patient and offering adequate lubrication.

With the aid of a strong light, the cervix is now visualized directly. Size, position and length of the cervix, as well as the nature of its secretions, are noted. This is the moment at which an old adage becomes most significant: "Examine the cervix with a strong light and with a suspicious mind." A smear for study by the Papanicolaou technique may be taken; secretion should be taken from both the internal os and the vaginal pool. Samples may be taken with the use of either a wooden spatula or a cotton applicator. The secretion is spread on a clean glass slide which is dropped immediately into a solution of 95 per cent alcohol. Because of the danger of explosion, ether should not be added to the solution of alcohol stored about the offices.

Next, the cervix is inspected for evidence of cystic change, lacerations or erosions. A specimen of tissue can be taken for biopsy, if biopsy is indicated. A specimen of any abnormality that is seen should be taken for biopsy before definitive therapy is offered. Such a specimen should be obtained in the presence of all cervical erosions, and care should be exercised to obtain adequate tissue from the squamocolumnar junction. This should always be done before cervical cautery is attempted. The application of Lugol's solution will demarcate those areas most applicable for biopsy.

You will recall that normal cervical and vaginal epithelium contains glycogen, whereas abnormal epithelium, such as that found in erosions or a malignant lesion, contains little or none at all. Hence, by applying a weak solution of iodine (¼-strength tincture of iodine) to these areas, a marked differentiation may be seen rapidly; normal tissue taking a deep mahogany brown, the pathologic a pink. It is from the pink or light areas that specimens for biopsy should be taken. One must be cognizant of the fact that the Schiller or iodine test is not specific for any type of lesion, nor does it distinguish malignant from benign tissue. All it does is to demarcate the areas from which specimens of tissue for biopsy should be taken. There is no special time in the menstrual cycle when the specimen for biopsy should be taken; the important factor is to do it when the patient is seen. In this regard, the endocervix should not be neglected, because the introduction of a small sound or cotton applicator within the cervical canal (the so-called Clark test) will many times disclose a pathologic process which otherwise might have been missed.

Many women present themselves with bleeding after subtotal hysterectomy. Under such circumstances, a small endocervical curet may be used to obtain tissue for examination. If small endocervical polyps are the cause of the bleeding, this curettage may be therapeutic as well as diagnostic. It is always well to submit all such material to a competent pathologist for careful examination and evaluation.

It is also a wise practice to remove all polyps which may be found extruding from the cervix. Polyps can be removed easily by torsion; this should be followed by fulguration of the bases of the polyps. All polyps should be examined by a competent pathologist. Before the speculum is removed, the condition of the pelvic walls should be observed, with attention to the presence or absence of excoriations or new growths.

The bimanual examination, which would better be known as the "vaginal-abdominal examination," can be done with either the left hand or the right within the vagina. From a practical standpoint, and especially in the case of those physicians who practice obstetrics, I believe it is useful to develop ambidexterity in the performance of this examination. With the examiner's fingers resting against the pelvic floor, the cervix is palpated, while the examiner's other hand is placed flat on the lower part of the patient's abdomen. By elevating the palm and using the tactile sense in the balls of the fingers rather than in the tips, the various organs are located, steadied and evaluated. The size, shape and consistency of each structure can be determined, and if tumors project into the superior strait, their outlines can be noted.

After the cervix has been palpated, the presence or absence of pelvic pain on motion is determined. The position of the uterus is ascertained by locating the body of the uterus. When the uterine fundus lies in its normal relationship, it is usually in an anteflexed position. Retrocession or retroflexion occurs normally in a high percentage of women. The mobility of the uterus may be then thoroughly tested. Immobility or excessive pain on uterine motion may be indicative of chronic infection, acute exacerbation of chronic infection, adhesions or endometriosis. When the median part of the pelvis has been palpated and the condition of the uterus has been determined, the examining fingers are now slid into one of the fornices lateral to the uterus. The abdominal hand is directed in a like plane, and is moved slowly and deliberately.

Next, the examiner's fingers in the vagina are pushed out into the lateral fornix, while the hand resting on the abdomen is directed in a like plane. The ovary is then palpated between the tips of both fingers. A normal ovary is sensitive and mobile. Ovaries which are retrocessed within the pelvis are best examined later by rectoabdominal approach. The physician should become familiar with the normal size of an ovary and should keep in mind its tendency to enlarge after contralateral oöphorectomy and hysterectomy. The normal ovary feels like an almond; it is about 4 cm. long and 2 to 3 cm. wide. Normally, it will move within a limited range. Occasionally, its mobility may become abnormal and it may be situated immediately lateral to the cervix, within the cul-de-sac, or high on the lateral pelvic wall.

Normal fallopian tubes usually cannot be palpated through the vagina; however, if they are thickened or are the sites of chronic residual changes from infection, they may be sensed as masses of hornlike shape which occasionally are fluctuant, and many times are tender, firm and resistant.

Occasionally, it is possible to palpate the ureters, lying as they do on the lateral pelvic wall. If pyelonephritis is present, the ureters may be thickened; if tuberculosis is present, they may be nodular. Ureteral calculi occasionally can be palpated; inflammatory conditions within the ureters may provide their own clues by making the ureters unusually tender.

Rectal examination should be done for all patients who complain of difficulties referable to the pelvis, and it is especially indicated for young women with an intact hymen. When a pelvic malignant process is present, the rectoabdominal examination gives perhaps more information than any other. The necessity for an empty bowel is clear. Care should be taken not to exert too much pressure against the anterior wall of the bowel, for that structure may be extremely tender. Should any abnormalities be noted, proctoscopic examination is indicated.

Lesions within the vagina and cervix occasionally may be seen best by examination with the patient in the knee-chest position. The vagina is easily distended with air, making the vaginal rugae disappear, and allowing the walls of the vagina to be seen clearly. Examination of children and young girls is best done with the patients in this position, and with the aid of a Kelly cystoscope.

At times, it may be necessary to carry out pelvic examination with the patient anesthetized. This is indicated only after repeated pelvic examinations have been entirely unsuccessful, sometimes with several days intervening. We should be aware not only of the usefulness of this procedure, but also of its limitations. Naturally, examination of the pelvis with the patient under anesthesia has no value under conditions in which the cooperation of the patient is needed; for example, to locate areas of pain or minimal discomfort. In general, the more complete and accurate the pelvic examination is, the less frequently need one resort to anesthesia in gynecologic diagnosis.

Laboratory Aids.—A paper on the pelvic examination of course is not complete without brief mention of some of the laboratory facilities which aid in the diagnosis. These should include urinalysis, complete blood counts, determination of the sedimentation rate, serologic tests for syphilis, smears and culture of specimens of urethral and cervical secretions, and finally, the taking of special smears for the Papanicolaou technique of detection of malignant cells. Specimens of cervical tissue should be taken for biopsy if the examiner believes this laboratory procedure is indicated.

It is well to emphasize again that all laboratory procedures should be supplemental to clinical observation and carefully performed bimanual examination. Preceded by a carefully taken history, the value of any laboratory test is dependent upon the clinician's ability to interpret the findings and correlate them with what he has found by direct examination of the patient.

The Treatment of Anemia

CHARLES H. WATKINS, M.D.
Rochester, Minnesota

IN ANY consideration of the treatment of anemia, it is important to recognize that anemia is not a disease in itself but merely a symptom resulting from some underlying cause. Therefore, one must establish the etiologic factor involved in the anemia prior to therapy.

Hypochromic (Iron-Deficiency) Anemia

The great majority of anemias are of the iron-deficiency type and usually are secondary to chronic loss of blood, to inadequate intake or inadequate absorption of iron, or to the so-called physiologic deficiency of iron. Morphologic examination of the erythrocytes reveals a decrease in hemoglobin within the cell, with resultant hypochromasia. The erythrocytes are usually normal in size, although some regenerative macrocytes may be present; in some instances the erythrocytes may be smaller than normal. Regenerative macrocytosis with increased polychromatophilia may be noted, particularly if the loss of blood has been severe. A proportionate reduction in the number of erythrocytes usually occurs in acute hemorrhage; however, in this case the cells rarely show a loss of hemoglobin unless an associated hypochromic anemia of some duration has been present prior to the onset of the acute hemorrhage.

It is important to ascertain, insofar as possible, whether any loss of blood has occurred in a person who has hypochromic anemia. Loss of blood with menses frequently may produce a rather pronounced hypochromic anemia. Bleeding from the gastrointestinal tract is relatively common. Such bleeding may originate from ulcers, carcinoma, polyps, varices or hemorrhoids; various hemorrhagic diseases may be manifested initially by bleeding from the gastrointestinal tract. In a patient who has an obscure anemia, one should examine the stools for evidence of occult blood and a thorough gastrointestinal investigation should be done.

Under modern conditions, anemia associated with an inadequate intake of iron is relatively rare. A well-balanced diet in the northern part of the United States contains approximately 10 mg. of iron daily. The gastrointestinal tract is able to absorb approximately 0.5 to 1.5 mg. of iron daily; this absorption occurs at a constant rate even when there may be unusual demands for iron by the body. The normal excretion of iron is approximately 1 mg. daily. In certain instances it is well to obtain a detailed description of the patient's diet if other etiologic factors cannot be elicited in the investigation of hypochromic anemia.

Anemia due to physiologic deficiency of iron may occur in several conditions. In infancy there is usually an inadequate intake of iron as well as a period of rapid growth with a rapid increase in blood volume; consequently, the relative deficiency of iron results in hypochromic anemia. This same condition may prevail during periods of rapid growth in later years, particularly at the time of puberty. At such times the great increase in blood volume may be accompanied by a relative decrease in the amount of iron available, with development of hypochromic anemia. At the onset of menstrual flow, blood may be lost at a time when rapid growth is still occurring, producing a double demand for iron; in such instances, rather severe degrees of hypochromic anemia may appear. The so-called physiologic anemia of pregnancy is due in part to the fact that within a relatively short period a great increase in blood volume occurs with a relatively constant intake of iron; thus, iron-deficiency anemia may occur.

Practically all persons can absorb iron from the gastrointestinal tract. The iron is absorbed in the form of ferrous salts and the chief site of absorption is the duodenum. As already indicated, an extremely small amount of the iron in-

The Mayo Foundation, Rochester, Minnesota, is a part of the Graduate School of the University of Minnesota.

gested is actually absorbed and, after hematologic values have been restored to normal by administration of iron, it is well to continue the treatment for a month or so in an attempt to supply the body with sufficient stores of iron. Protracted treatment after that time is usually not advisable.

When an anemic patient takes iron, the peak of the response of reticulated erythrocytes occurs in about eight to twelve days, which is about the same time at which it occurs in the treatment of pernicious anemia with effective fractions of liver or vitamin B_{12}. Since administration of iron is the treatment of choice in iron-deficiency anemia, the use of liver extract, vitamin B_{12}, folic acid and other similar substances is not indicated.

Practically all patients respond to the oral use of iron. However, an occasional patient cannot tolerate iron given by mouth. Also, in certain severe hypochromic anemias it may be desirable to obtain a rapid increase in the value of hemoglobin. In such situations, the intravenous injection of iron is of value. Several formulas for the calculation of the amount of iron needed intravenously to bring the hemoglobin to a normal level can be found in the literature. The simplest one is based on the fact that approximately 25 mg. of metallic iron is required to increase the value for hemoglobin by 1 per cent. This provides an easy method of calculating the amount necessary. The preparation used is a solution of saccharated iron oxide in a dose of 100 mg. injected intravenously once or twice daily. Care should be taken to determine that the material is not unduly toxic for a given patient and a small initial dose should be used. If an untoward reaction does not occur, the patient usually will tolerate larger doses. Actually it is rarely necessary to resort to intravenous therapy, as practically all patients respond satisfactorily to iron given orally.

Macrocytic Anemia

Among the various types of macrocytic anemia, often termed "megaloblastic anemia," the commonest is pernicious anemia. Fortunately this form of anemia responds well to adequate therapy. The clinical findings in pernicious anemia may vary but in general they include anemia, glossitis with atrophy of the mucous membrane of the tongue, a history of pernicious anemia in the family, early gray hair, evidence of combined system disease, absence of free hydrochloric acid in the gastric contents, and intestinal manifestations, which may be characterized by loose watery stools or by constipation alternating with loose stools. As a rule, patients who have pernicious anemia do not lose weight and may have a relatively abundant amount of subcutaneous fat. They often display a surprising amount of energy for the degree of anemia that is present; this is probably due to the fact that, because of the gradual onset of anemia, the body becomes accustomed to the anoxemia.

Examination of blood smears in pernicious anemia reveals generalized macrocytosis, with the erythrocytes usually containing normal amounts of hemoglobin. There is usually an increase in poikilocytosis or the appearance of pear-shaped erythrocytes, which is thought to be due to loss of elasticity of the cellular membrane. The leukocyte count is usually normal but may be decreased or even increased. Megaloblasts or normoblasts may be present in severe degrees of pernicious anemia and thrombocytopenia occasionally may be noted. More rarely, a leukemoid reaction may occur in severe degrees of pernicious anemia. An occasional patient who has pernicious anemia in crisis may have a leukocyte count as high as 40,000 or more cells per cubic millimeter of blood, with a great increase in immaturity, so much so that the presence of acute leukemia may be suspected in an occasional case. Examination of the bone marrow reveals the presence of megaloblasts, which, together with the clinical findings, usually enables one to establish the diagnosis of pernicious anemia. The polymorphonuclear neutrophils usually exhibit thinning of the individual lobes, with stranding between the lobes. Hyperlobulation may occur, with as many as six to twelve lobes, or even more, being present. This type of neutrophil, although not absolutely diagnostic, is the so-called pernicious-anemia neutrophil and its appearance, with other findings in the peripheral blood, would make one suspicious of the presence of this disease.

After the diagnosis of pernicious anemia is established, the treatment is relatively simple. The most important factor is to give effective doses of liver extract or vitamin B_{12}. Depending somewhat on the degree of anemia, I prefer to start treatment with fairly large doses. If concentrated liver extract is used, an initial dose of 3 cc. (45 units) is given; if vitamin B_{12} is used, the initial dose is 60 micrograms. This dose is given intramuscularly once daily for three successive days. Then 1 cc. of liver (15 units) or a dose of 30 micrograms of vitamin B_{12} given once a week usually restores the blood to a normal level, after which time a maintenance dose may be worked out. In the uncomplicated case, this dose averages about 15 units of liver extract or 30 micrograms of vitamin B_{12} every two to four weeks. Some persons require more than others. In the presence of combined system disease, a larger dose of an effective fraction may be necessary, such as 30 units of liver extract or 60 micrograms of vitamin B_{12} twice a week, which may be continued for a number of months depending on the degree of improvement in the combined system disease.

Proper maintenance therapy consists in giving a sufficient amount of an effective fraction to keep hematologic values at normal levels, to avoid macrocytosis and to prevent any advancement of neurologic symptoms or to improve them, if it is at all possible. Sometimes a patient may be receiving maintenance doses of liver extract and getting along satisfactorily; in spite of this, the symptoms and findings of combined sclerosis will develop. In such instances, larger doses of the effective agent are required.

There is practically no difference between the response obtained from vitamin B_{12} and that obtained from liver extract. One slight difference is that liver extract exerts a slight effect on the coagulation of blood that is not produced by vitamin B_{12}. This is relatively unimportant and is of no consequence with regard to the management of pernicious anemia. The main factors are to give sufficient material for control of the neurologic symptoms and to keep the patient on sustained and steady treatment for the rest of his life.

Parenteral administration of liver extract or vitamin B_{12} is in general the treatment of choice. As a rule this method is cheaper, it permits the physician to keep the patient under observation so that he can determine whether or not the treatment is adequate, it impresses on the patient the importance of regular therapy and it assures that the material is absorbed. Vitamin B_{12} has what might be considered some advantages over liver extract in that it is a purified crystalline substance of constant potency, it may be used in patients who are sensitive to liver extract and it produces a minimal local reaction. Oral therapy for pernicious anemia produces a satisfactory remission and patients may be maintained satisfactorily by such treatment. However, at present it is usually expensive, absorption may vary greatly depending on the condition of the gastrointestinal tract at a given time and in general it is difficult to maintain adequate control of the patient by such therapy.

Folic acid is known to be important in the maturation of erythrocytes. It will convert a megaloblastic bone marrow to a normoblastic state and will correct the hematologic abnormalities associated with pernicious anemia. However, glossitis and the symptoms of combined sclerosis may develop in many patients while folic acid is being given. Consequently its use is not advisable although it is not contraindicated. Essentially the same is true for citrovorum factor, or so-called folinic acid, another substance that has been shown to be necessary for the conversion from a megaloblast to a normoblast. Folic acid and citrovorum factor are effective either orally or parenterally but neither of them exerts any beneficial effect on combined system disease. They usually have no effect on the gastrointestinal symptoms in pernicious anemia. Citrovorum factor, however, is important in that it is of great value in combating the toxic reactions to antifolic substances that have been used in the treatment of certain leukemias. Combination therapy with liver extract and iron is rarely needed because in most instances the stores of iron in pernicious anemia are at a high level. Administration of hydrochloric acid as a rule is not necessary in the management of pernicious anemia.

The treatment of other types of megaloblastic anemia is often extremely difficult. It usually may be summed up as a method of trial and error, utilizing various substances that are essential for hematopoiesis. Megaloblastic anemia other than pernicious anemia may occur as the result of gastrointestinal disease, total gastrectomy, intestinal strictures and fistulas, or short-circuiting operations; nutritional macrocytic anemia is seen in the tropics and with sprue, either tropical or nontropical. Megaloblastic anemia also may be associated with pregnancy; this is the so-called pernicious anemia of pregnancy, which is usually due to a deficiency of folic acid. Use of liver extract or vitamin B_{12} may produce improvement; otherwise, folic acid may be of value. The megaloblastic anemia of infancy usually can be corrected by use of folic acid, although in some instances liver extract or vitamin B_{12} may prove effective. The megaloblastic anemia associated with infestation by the fish tapeworm shows a variable response to the administration of vitamin B_{12} or folic acid.

The treatment of megaloblastic anemia other than pernicious anemia is probably best begun by use of vitamin B_{12} in the same dosage as would be used in treatment of pernicious anemia. If no response occurs after two or three weeks, use of folic acid may be tried. If there is still no response, folinic acid or citrovorum factor can be used. Transfusion may be necessary in some cases because of lack of response to any of these substances. Occasionally, a rare macrocytic anemia may occur with a relatively aplastic bone marrow that will respond to administration of cortisone, following which the blood responds to use of folic acid or vitamin B_{12}. In refractory anemias, such treatment might be tried.

Anemia in Systemic Diseases

Anemia is a frequent finding in many systemic conditions for which treatment is of practically no value. Examples of such anemias are those associated with metastatic malignant lesions involving the bone marrow, nephritis with azotemia and the anemia associated with infection. In azotemia, if it is possible to decrease the blood urea, the patient's blood usually will respond automatically. In true hypoplastic or aplastic anemia, treatment is of little or no value. The same is true of the leukemias and lymphoblastomas. The anemia associated with rheumatoid arthritis rarely responds to any of the usual hematinics. The anemia associated with myxedema responds to administration of desiccated thyroid but usually fails to respond to any other substance.

In conclusion, it is important to establish the diagnosis and the etiologic factor responsible for the anemia before treatment is started. In certain instances, treatment of anemia may mask an underlying serious disease whose early diagnosis would save the patient's life.

DIGESTIVE AILMENTS OF OLDER PATIENTS

(Continued from Page 314)

the background of the patient, his habits and his way of life, and who can, by persuasion and advice, do much to ameliorate these symptoms.

Summary

An attempt has been made to show the frequency, distribution and severity of benign digestive disorders in the aged. In many instances, the complaints, however bizarre and atypical, are likely to have an organic background. The diagnosis of the organic disease is often far from easy, chiefly because the usual clues which lead to diagnosis are absent or distorted. If the history is brief, full investigation is compulsory. If it is a continuation of one which has plagued the patient all his life, investigation is still essential, if only to provide the necessary reassurance and support essential to treatment. Symptomatic treatment without full investigation is at its best a risky business and temporizing on such a basis is the cause of much disability and many fatalities in the aged. It should not be forgotten that persons who reach the eighth decade of life are of a rather special pattern and mold, and not infrequently are made of better biologic materials than their juniors. Their tolerance to surgery may be amazingly good and their recovery from even major procedures rapid. Here is a field in which all physicians can participate in reducing mortality and morbidity rates, and in making life more bearable for many people who have passed their prime.

CARCINOMA IN SITU OF THE UTERINE CERVIX

DAVID C. DAHLIN, M.D.
Rochester, Minnesota

Carcinoma *in situ* is a lesion in which epithelium in its normal anatomic location possesses the cytologic criteria for malignancy. It has not broken through the anatomic barrier that separates the epithelium from the underlying connective tissue. Such preinvasive or intraepithelial carcinoma has been observed in many sites, including the skin, the mammary ducts and acini, colon, stomach, bronchi, larynx and uterine cervix.

Intraepithelial carcinoma of the cervix has been recognized for more than thirty years. However, large series of cases have accumulated only during the past decade, as a result of development of intensive programs for the early detection of cancer. Investigators have established some facts concerning this phase of cervical carcinoma and have emphasized some other problems relating to it that as yet are unsettled.

Knowledge of the established facts is necessary to an understanding of the controversies. Carcinoma *in situ* is ordinarily invisible. Most of these early malignant lesions are discovered when a smear or a specimen for biopsy is procured from a grossly normal cervix or one that has an erosion, an eversion, leukoplakia or "cervicitis." Application of Lugol's solution may outline the neoplastic lesion when it is otherwise invisible; normal cervical mucosa stains dark brown owing to a high glycogen content of the cells, whereas little or no staining occurs in the malignant cells, which are deficient in glycogen.

Carcinoma *in situ* nearly always begins at the squamocolumnar junctional zone. This line is usually at the external cervical os but may lie well out on the portio vaginalis or up in the cervical canal. Those *in situ* carcinomas associated with leukoplakia may arise any place on the cervix and even in the vagina. Downgrowth of this surface carcinoma into the mucous glands of the cervix is common and may be extensive. Such spread does not impart a metastasizing potential in the absence of true stromal invasion, because the basement membrane of replaced glands acts as a barrier to lymphatic and hematogenous dissemination.

In situ carcinoma may be as small as a square millimeter and involve only a minor portion of the circumference of the squamocolumnar junctional zone. However, it may spread to involve large regions of the portio vaginalis and even, though rarely, the upper part of the vagina. This surface lesion also may extend 2 or 3 cm. up to the endocervical canal.

The accessibility of the uterine cervix to inspection and for procurement of specimens adapts it well to cytologic techniques for early detection of cancer. *In situ* or early infiltrating cervical malignant tumors that are invisible can be unmasked with a high degree of accuracy by study of stained smears of scrapings from the exocervix and endocervix. Tissue for biopsy that includes the squamocolumnar junctional zone taken from each quadrant of the cervix provides a similarly great accuracy of detection.

Cervical carcinoma *in situ* appears to be present in about 1 per cent of adult females. Practically equal numbers of these lesions can be detected by good cytologic screening, by careful biopsy techniques or by a combination of the two. Sizable variations from this usual rate of prevalence indicate differences in the criteria for carcinoma accepted by some pathologists or in the efficiency of the detection program.

Debates concerning some of the controversial phases of this subject can hardly add real knowl-

edge, although they do bring known facts into focus. Scientific statistical evaluations of the type contributed by Dunn[1] likely will supply the ultimate answers. Unwillingness to submit human beings to periods of observation of intraepithelial carcinoma hampers acquisition of knowledge. Evaluation of recorded studies is clouded by the fact that biopsy sometimes eliminates the entire lesion, as can local cautery.

Does uterine carcinoma *in situ* usually progress to infiltrating carcinoma and is the latter ordinarily preceded by the former? More than forty instances of such progression have been documented, and a lesser number of these preinvasive carcinomas reputedly have regressed.[2] Limited data suggest that a preinvasive phase usually precedes clinical carcinoma of the cervix.

How long is the latent period, the time from which intraepithelial carcinoma is histologically recognizable until it produces clinical carcinoma? The average difference in age of patients at the time of detection of each form of lesion indicates an interval of about eight years. Since detection of the asymptomatic and invisible carcinoma *in situ* is a matter of chance, the average lesion in a screened population is found at about the midpoint in its evolution from histologic recognizability to clinical invasiveness. Accordingly, it is likely that the preinvasive phase lasts about twice as long as the ages at detection would indicate, or about fifteen years.

The likelihood that preinvasive carcinoma incubates for more than a decade lends credence to its significance. Statistically, the average prevalence of the *in situ* lesion and the recorded incidence of development of clinical cervical malignancy are consistent with the view that the former is the precursor of the latter. Additional validity for the concept of carcinoma *in situ* is afforded by other facts. Jewish women enjoy the same relative immunity for this incipient lesion that they are known to have for clinical carcinoma of the cervix. Recognizable malignant cells appear in smears in both stages of the disease. Typical intraepithelial carcinoma is frequently found at the periphery of ulcerating cervical carcinoma. The full-blown picture of carcinoma in situ probably is valid diagnostically during pregnancy, although some investigators caution against overdiagnosis of epithelial hyperplasia in the pregnant state.

Controversial criteria have been suggested for establishing that a given carcinoma is still *in situ.* The experience of my associates and me[3,4] indicates that study of a section made from each of about twelve serial blocks of the entire squamocolumnar region at right angles to the junctional zone is adequate. Minimal evidence for true invasion includes obvious vascular invasion or stromal permeation, the latter often accompanied by a scirrhous reaction to the penetrating cells.

What treatment should be given for carcinoma *in situ?* Hysterectomy alone is curative except for the rare case in which surface spread past the line of excision in the upper part of the vagina has occurred. Some physicians consider that conization of the junctional region or extensive cautery is adequate. Extensive surface spread to the exocervix or vagina or up the cervical canal imposes obvious limitations on either of these procedures. The more radical procedures, including Wertheim hysterectomy with dissection of the pelvic lymph nodes and conventional radiation therapy, are unnecessary.

Case Reports

HEMOBILIA FOLLOWING BLUNT TRAUMA TO THE LIVER

H. M. BROKER, M.D., and L. J. HAY, M.D.
Minneapolis, Minnesota

Hemobilia is a term used to designate hemorrhage into the biliary tract as a result of trauma to the liver. Fourteen cases are reported in the collected literature which has been reviewed by Sandblom,[3] by Sparkman,[4] and by Sparkman and Fogelman.[5] We wish to report two additional cases.

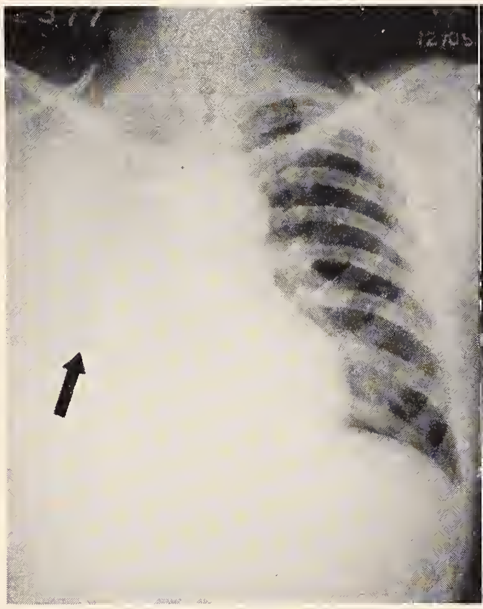

Fig 1. Case 1. Postoperative chest roentgenogram taken on December 10, 1953, showing a right pleural effusion with an air fluid collection under the right diaphragm.

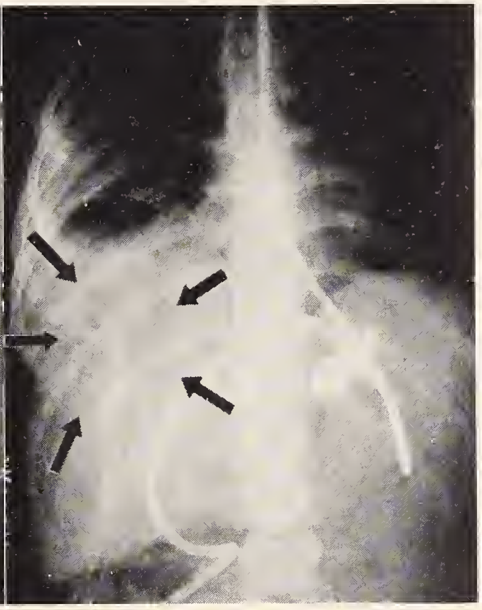

Fig. 2. Case 1. Postoperative roentgenogram of the abdomen after choledochostomy. This view shows the developing area of emphysematous tissue under the right diaphragm and a large air bubble present in that region.

Case Reports

Case 1.—D. U., a twenty-five-year-old white man was admitted to the Minneapolis Veterans Hospital on November 22, 1953, sixteen hours after having been in an automobile accident. The patient suffered no apparent injury at the time of the accident and was taken home by a passing motorist. Shortly after arriving home, he developed abdominal pain and a physician was called. When examined by the doctor the patient was in shock. A transfusion of 1000 cc. of whole blood was given at the local hospital and he was transferred to this hospital for definitive treatment.

Physical Examination.—On admission, the blood pressure was 90/60 and the pulse was 120 beats per minute. Examination of the head, neck and chest was normal. The abdomen was moderately distended and generalized rebound tenderness and spasm were present. There were no abrasions of the thorax or abdomen.

Laboratory Examination.—The hemoglobin was 12 Gm./100 cc. blood. The urine was normal. The flat and upright roentgenograms of the abdomen were not diagnostic.

Hospital Course.—Shortly after admission, the patient vomited 2000 cc. of grossly bloodly fluid. A transfusion of 1500 cc. of whole blood was given rapidly, after which the hemoglobin was reported as 11.7 grams. The blood pressure rose from 90/60 to 130/80 but the pulse remained at 130.

The patient was operated upon. Approximately 3000 cc. of blood was present in the peritoneal cavity. The capsule was torn free from an area of the dome of the right lobe of the liver. The laceration was estimated as 8x12 cm. in dimension. Liver tissue and blood clots were scooped out to a depth of 3 or 4 cm. The wound was

---

Dr. Hay, formerly Chief of the Surgical Service, Minneapolis Veterans Hospital, Minneapolis, is now Director of Surgical Research, Mount Sinai Hospital, Minneapolis.

packed with gelfoam. Two large rubber tube drains to the area were brought out in the right flank posteriorly under the margin of the twelfth rib. Postoperatively, the patient's temperature remained at 100-101 degrees F. There was a large amount of bile drainage (Fig. 1). It was suggested that, since most of his bile was draining through the posterior drain, a decompression of the biliary tract be performed. On December 18, 1953, a choledochostomy was performed. This was followed by a marked decrease in the bile drainage from the wound.

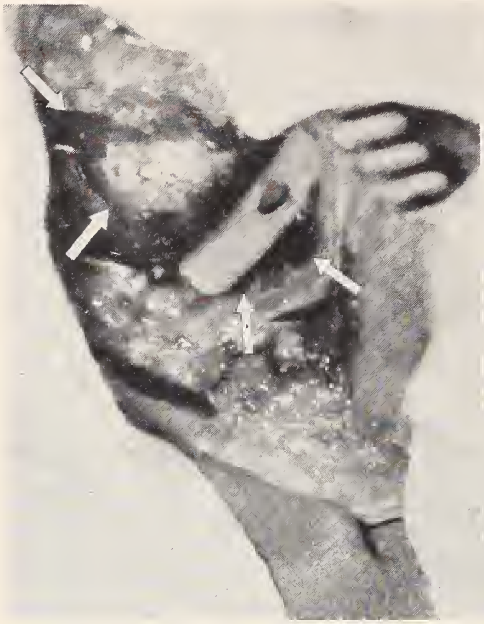

Fig. 3. Case 1. The large cavity is seen on roentgenogram in Figure 2 as an emphysematous area. The cavity is filled with necrotic liver tissue which is shown in Figure 4.

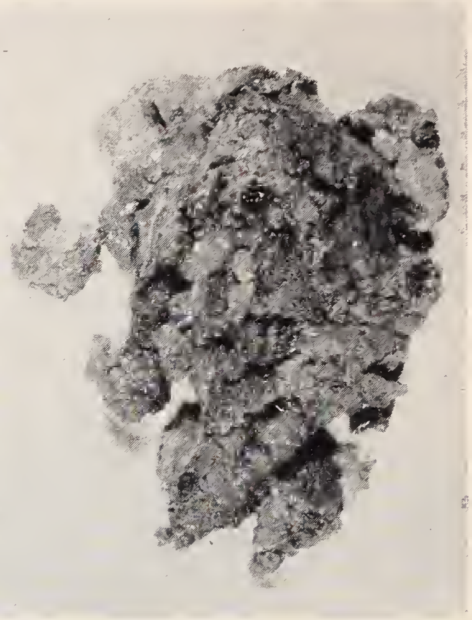

Fig. 4. Case 1. The resected specimen of necrotic liver tissue from the right lobe. This tissue is seen on the roentgenogram in Figure 2, represented by the area of emphysematous reaction.

On December 24, 1953, a peculiar emphysematous mass with a fluid level was noted under the right diaphragm on the roentgenogram (Fig. 2). This mass was explored through an incision traversing the tenth rib bed and diaphragm, and a sequestrum of necrotic liver tissue, 10 cm. in diameter was removed. The sequestrum was separated from the viable liver tissue by a fibrotic layer. It was removed by finger dissection. Brisk bleeding was controlled by a gelfoam pack. It was estimated at the time of surgery that about 30 per cent of the right lobe of the liver had sequestrated (Figs. 3 and 4).

Postoperatively, the patient developed a stenosing esophagitis involving all the esophagus beyond the aortic arch. This was satisfactorily controlled by dilatation. Healing of the liver defect was slow but progressive and was complete after four months.

This patient has been followed for one year. Liver function tests were within normal limits on December 13, 1954. The patient is completely asymptomatic and is working.

Case 2.—P. H., a twenty-year-old white woman was admitted to the Minneapolis General Hospital on June 19, 1954, following an automobile accident. On admission, she was irrational and uncooperative.

Physical Examination.—Blood pressure was 94/54, the pulse was 100 and the temperature was 98 degrees F. Findings included a large hematoma of the forehead, tenderness over the right lower chest, and abdominal rigidity with marked tenderness present in the right upper quadrant. Bowel sounds were absent.

Laboratory findings were essentially normal with the exception of a hemoglobin of 10 Gm./100 cc. blood.

Hospital Course.—A peritoneal tap performed on admission was negative. After the patient had received 1000 cc. of whole blood, her blood pressure stabilized at 130/80, and a laparotomy was performed. The peritoneal cavity contained approximately 2000 cc. of blood. Examination of the liver revealed a 5 x 10 cm. stellate laceration of the dome of the right lobe.

The laceration of the liver was packed with gauze and a large Penrose drain was placed to Morison's pouch and to the area of laceration.

The drains and pack were removed and the patient was asymptomatic by July 4, 1954.

On July 12, 1954, the patient became febrile and complained of right upper quadrant pain. This was followed by one episode of hematemesis, after which the hemoglobin was 8.8 Gm. A transfusion of 1000 cc. of whole blood was administered, and the hemoglobin was then 12 Gm. The pain in the right upper quadrant continued intermittently until July 20, 1954, when it became severe and radiated to the back. On that day the hemoglobin dropped to 8.0 Gm.

On July 21, 1954, after the patient had been given a transfusion, a laparotomy was performed. The gall bladder was filled with clotted blood. The subphrenic space was explored and contained a "deep purplish" exudate. Brisk bleeding occurred from the lacerated area of the liver and was controlled by repacking with gauze. A cholecystostomy was performed and the abdomen was drained.

The pack was gradually removed over a two-week period. The patient was asymptomatic until August 10, 1954, when mild right upper quadrant pain occurred. Three hours later the pain had become severe and the patient began to bleed profusely from the site of the previously removed subphrenic drain and through the cholecystostomy tube. In a two-and-one-half-hour period, the patient received 7500 cc. of whole blood. The patient died in the operating room from shock before definitive surgery could be accomplished.

Rochester, Minnesota

IN SPITE of our present-day accuracy of neurologic and ophthalmologic diagnosis, a neurologic surgeon must be prepared for unexpected developments when he opens a patient's skull.

The diagnosis of a chromophobe adenoma of the pituitary gland usually is not difficult. The visual loss which causes the patient with such a lesion to consult a neurosurgeon ordinarily is rather classic, and the roentgenologic finding of an enlarged and eroded sella turcica is most often pathognomonic of a pituitary tumor, yet occasionally the surgeon uncovers a lesion that is entirely unexpected. The following report is illustrative of the unexpected situation that may be encountered once in a while.

Case Report

A sixty-five-year-old woman came to the Mayo Clinic complaining chiefly of poor vision in her right eye. The decreased vision on the right had been noticed for about five months. A local ophthalmologist had prescribed "drops"; these had been used without improvement. Two weeks before coming to the clinic this patient saw another ophthalmologist, who examined her eyes and advised roentgenologic examination of her head, which was done. The patient said he told her she had a "boil" in her head, and that it needed to be "dried out" with x-ray treatments. A neurosurgeon saw her and was said to have concurred in the diagnosis and treatment. During the two weeks prior to the patient's visit to the clinic the husband had noted a slightly increased prominence of her right eye.

In addition, the patient complained of mild bitemporal and biparietal headache. There had been no symptoms to suggest endocrine dysfunction.

The patient was 59¼ inches tall and weighed 148½ pounds without her clothes. There were no physical signs of pituitary insufficiency. The blood pressure was 178 systolic and 108 diastolic, measured in millimeters of mercury. The uterus was surgically absent (hysterectomy had been done in 1930). Vision was recorded as 6/20 on the left and 1/60 on the right. There was 1 mm. of proptosis of the right eye. The palpebral fissure was 2 mm. wider on the right than on the left. Extra-ocular motions were generally restricted in all directions in the right eye. The tension in the right eye was 27, whereas in the left eye it was 20. The ocular fundi revealed a moderate degree of pallor, and the arterioles of the retina showed the changes of chronic hypertension.

The fields of vision when plotted revealed bitemporal hemianopsia, with involvement of the right optic nerve and right side of the optic chiasm.

Neurologic examination did not disclose any additional abnormalities. Roentgenologic examination of the head demonstrated erosion and enlargement of the sella turcica, which condition was interpreted as being due to a large intrasellar tumor (Fig. 1). Roentgenograms of the optic canals showed them as normal. The superior orbital fissure on the left was slightly larger than that on the right. This was thought to be of no clinical significance.

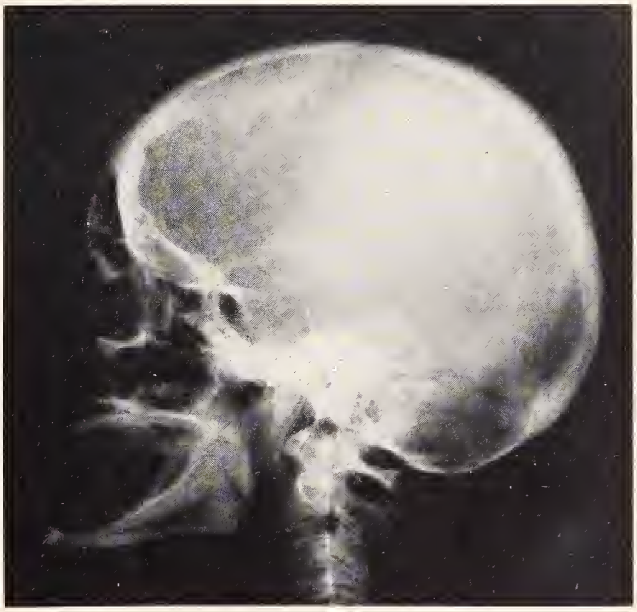

Fig. 1. Lateral roentgenogram showing enlargement and erosion of the sella turcica, such as is seen in the presence of a pituitary tumor.

The basal metabolic rate was within normal limits (+6), as were results of blood counts and urinalysis.

We knew we were dealing with a progressive lesion involving the sella turcica and the visual apparatus. We felt the lesion was neoplastic and not an aneurysm of the carotid artery or the circle of Willis. In an attempt to explain all the ophthalmic signs and the eroded sella turcica we considered three different neoplasms which might be conceived to be present, and we assigned the following percentages, in terms of likelihood, to each: meningioma, 50 per cent; pituitary adenoma, 40 per cent; pituitary adamantinoma, 10 per cent.

Operation for the removal of a tumor involving the visual apparatus was advised and accepted.

Dr. Love is in the Section of Neurologic Surgery and Dr. Blackburn is in the Section of Medicine at the Mayo Clinic and Mayo Foundation. The Mayo Foundation in Rochester, Minnesota, is a part of the Graduate School of the University of Minnesota.

Although there was no clinical evidence of pituitary insufficiency, the patient was given 200 mg. of cortisone intramuscularly forty-eight, twenty-four and two hours prior to craniotomy. It was thought advisable to supply the patient with such a depot of cortisone in the event that operation resulted in acute anterior pituitary insufficiency, either temporary or permanent. After the operation the administration of cortisone was gradually reduced over a period of several days.

Right transfrontal craniotomy was performed with difficulty with a malleable needle. It was necessary to convert two of the perforator openings into burr openings, but we still were unable to turn the flap without lacerating the dura. There was sharp bleeding at the anterior temporal opening, and ultimately we realized why. After the flap had been turned, and as we were inspecting the lacerated dura, we noted a hard, firm, nodular mass in the anterior temporal hole and a thickened dura; this mass proved to be a typical meningioma of the Sylvian fissure, and it was of very respectable size. For a moment, it was thought that this process might be a lateral extension of a meningioma of the sphenoid ridge. However, this entire tumor mass was removed in one piece after the nutrient artery had been closed with silver clips and there seemed to be no deep extension.

Yet it was obvious that this tumor was not producing the defect in the visual fields or causing the erosion of the sella turcica. We then stripped the adherent dura from the roof of the right orbit and exposed the visual apparatus. As we did so, we saw a large, thick-walled, nonpulsating tumor projecting above the sella and extending under the right optic nerve and internal carotid artery, both structures being displaced upward. The tumor presenting between the optic nerves and anterior to the chiasm was aspirated without obtaining blood. Then it was incised and typical pituitary adenomatous tissue was obtained. A considerable amount of tissue was saved for microscopic examination. Most of the tissue within the capsule was removed with a sucker.

A large adenomatous extension under the right optic nerve and internal carotid artery was pulled within the sella and removed. Extensive resection of the capsule was carried out; a piece along the floor was left. The bleeding was under control. The lacerated dura was covered with a sheet of animal membrane. The bone was wired in place with two pieces of wire. The wound was closed in layers without drainage. The 30 cc. of fluid which had been removed through the malleable needle was replaced in the spinal canal.

The pathologist's report identified these lesions as (1) a meningioma of the Sylvian fissure, and (2) a chromophobe pituitary adenoma which was intrasellar, suprasellar and extrasellar (supratentorial) in extent.

The patient received 500 cc. of blood during these procedures.

The patient's postoperative convalescence was uneventful and very gratifying. For one twenty-four-hour period (the second) after operation the intake and output of fluids was markedly increased (4,800 cc. intake and 5,300 cc. output). However, this condition spontaneously subsided without the employment of posterior pituitary substance.

The patient was dismissed from the hospital on the eighth day after operation, and from the care of the Mayo Clinic four days later. At the time of dismissal there had been some improvement in vision in the temporal field of the right eye and ocular motions were normal.

HEMOBILIA

(Continued from Page 334)

Autopsy revealed an area of liver necrosis measuring 5 x 6 cm. There was an erosion of a branch of the right hepatic artery deep in the substance of the right lobe of the liver.

Discussion

The sparsity of reports in the literature would suggest that bleeding into the gastrointestinal tract as a result of liver injury is a rare condition.[1] It is more likely that bleeding is often mild or masked by the associated problems presented by other injuries.[2] Hemobilia may be an early or late complication of liver injury as in the two cases reported.

Central rupture of the liver occurs by compression of the inelastic and fragile liver parenchyma. When a tear occurs, arteries, veins, and bile ducts are ruptured and the cavity fills with blood and bile. This process produces necrosis which in turn produces secondary hemorrhage. The only exit of drainage in central laceration is into the bile ducts or the blood vessels. Autolyzing ferments at the site of injury, sequestration of damaged liver tissue and infection of devitalized tissue are other causative factors in the etiology of hemobilia.

Usually, hemobilia is an insidious process since the central portion of the liver has no sensory nerve endings. Only after the liver enlarges enough to distend the capsule or after a tear occurs in the capsule will pain be present. Shortly after the occurrence of bleeding into the bile ducts, the symptoms of typical biliary colic become manifest. This occurred in the second case reported.

Sparkman gives the symptoms of hemobilia as a triad of abdominal injury, pain, simulating biliary colic and gastrointestinal hemorrhage. In the second case reported, the patient experienced pain prior to the onset of hemorrhage and could predict the episodes.

Summary

Two cases of hemobilia are reported. In the first patient, the hemobilia occurred at the time of the injury, and in the second it occurred twenty-one days after injury.

Knowledge of this entity and the possibility of segmental necrosis of the liver substance should permit earlier debridement and decrease the chances of secondary hemorrhage.

Donald F. Gleason, Editor

CASE PRESENTATION

A. C. AUFDERHEIDE, M.D.
Duluth, Minnesota

The patient, a white nun, was originally admitted to St. Mary's Hospital in 1945 at the age of sixty-one for multiple contusions suffered when she fell while hanging curtains. Except for a fracture of a metacarpal bone, there were no other significant findings or complaints. At that time, the hemoglobin was 12 gm. per cent, red blood count 4,210,000/cu. mm. and white blood count 6,600/cu. mm. Recovery was uneventful.

The second admission was in 1946, at the age of sixty-two, for "strain of lumbar spine." While cleaning windows, she strained her back. She was admitted with severe pain in the lower back over the lumbar and sacral spine. There was local tenderness to deep pressure. Except for hyperactive tendon reflexes throughout, neurologic examination gave negative findings. The hemoglobin was 12.8 gm. per cent, white blood count 8,700/cu. mm., red blood count 4,320,000/cu. mm. Complete urinalysis showed no abnormalities. The spinal fluid showed 7 white cells/cu. mm., 64 mg. per cent sugar, 740 mg. per cent chlorides and 25 mg. per cent total protein. The colloidal gold curve and serology were normal. X-rays of the area were not remarkable except for slight wedging of the first and fourth lumbar vertebrae with hypertrophic changes which might represent old compression type fractures. The spinogram was negative for herniated intervertebral disc. The patient was fitted with a lumbosacral support and recovered uneventfully.

The final admission in February, 1954, occurred when the patient was sixty-nine. While sitting in a chair, she bent over, fell and struck the right hip, suffering immediate, severe pain in that area. Past history included pulmonary tuberculosis in 1907 for two months and a few minor surgical operations. System review revealed no abnormal findings except for blindness in the left eye for two years. Physical examination showed an obese white woman with severe pain in the right hip. A mature cataract was present in the left eye. The tongue was in the midline, and the pharynx showed no unusual changes. The chest was examined only anteriorly but showed no abnormalities. The blood pressure was 156/86 mm. of mercury. No other cardiac physical findings were present. The abdomen showed no abnormalities. There was an obvious fracture of the neck of the right femur. X-ray examination confirmed the fracture. A portable chest x-ray on the second hospital day was unsatisfactory, suggesting possible atelectasis on the right and an elevated right diaphragm. An electrocardiogram was normal. On the third hospital day, the hemoglobin was 16 Gm. per cent, the white blood count 14,500/cu. mm. with 73 per cent neutrophiles, 24 per cent lymphocytes. On the fourth hospital day, the hemoglobin was 14 Gm. per cent, platelets 135,300/cu. mm. A preoperative physical examination on the second hospital day showed a blood pressure of 150/80 mm. of mercury, pulse of 96, respirations 20/minute and temperature 100.2°; otherwise, there had been no change. The urine, which showed a specific gravity of 1.026, was otherwise normal. On the fourth hospital day, a hip-nailing procedure was carried out without difficulty. The patient progressed satisfactorily, and on the seventeenth hospital day she began to be up in a chair. On March 19, 1954, (thirty-third hospital day), the patient complained of a thick feeling in the tongue and difficulty in speaking. No other changes were found on examination. On March 22, she developed slurred speech as well as trouble in chewing and swallowing. The tongue deviated to the left. On March 24, she had two sudden episodes of dyspnea lasting about ten minutes each. The lungs were dry and the heart rhythm regular. On March 25, panting respirations were noted. An electrocardiogram repeated on this day was again normal. Neurological examination showed a nasal voice tone. Hypalgesia was present in the fifth finger and less in the fourth finger of the right hand. Deep reflexes were moderately hyperactive. Speech was difficult. Regurgitation of liquids occurred through the nose. No cerebellar signs were found. On March 26, a spinal puncture showed a pressure of 410 mm. water, and 4.5 cc. of clear colorless spinal fluid was removed. This contained no cells, but 45 mg. per cent sugar, 14 mgm. per cent total protein and 755 mg. per cent chlorides were present in the fluid. Pandy's test was negative, as were the gold curve and Wassermann tests. On this day the white blood count was 7,750/cu. mm., the hemoglobin 11.8 mg. per cent. On March 26, there was little change with no facial weakness detectable and an active gag reflex was present. On March 27, examination of the ear, nose and throat gave essentially negative findings. Pharyngeal muscle function was difficult to evaluate but all muscles moved as did the vocal cords. On March 29, the previous symptoms increased. On March 30, physical signs of diaphragmatic paralysis bilaterally were confirmed by fluoroscopy. The tongue became uncontrollable, and there was much respiratory distress. A tracheotomy was performed. Thoracic muscle action was poor. The patient was placed in a Drinker respirator. On March 31, her condition

---

From the files of the Department of Pathology, St. Mary's Hospital, Duluth, Minnesota. Discussed on June 25, 1954.

was grave with obvious signs of insufficient oxygenation. Slight nystagmus was apparent with the gaze to either side. The left palpebral fissure was narrower than the right. The left corneal reflex was less active than the right, and there was slight deviation of the tongue to the left. Her condition progressed to complete coma and death that night. The white blood count the day of death was 21,500/cu. mm., with 82 per cent neutrophiles. The temperature was normal throughout her illness until the day of death when it rose to 101 degrees.

Differential Diagnosis

Dr. L. R. Gowan: Review of the protocol as well as the nurse's notes indicate a rather marked fluctuation in the severity of symptoms from hour to hour. The past history also includes several falls with resultant fractures (ribs, ankle, wrist, hip). The x-rays served primarily to corroborate the clinical impression of diaphragmatic paralysis and also show no bone signs of hyperparathyroidism.

A broad view of the problem would demand consideration of many entities including:

1. Anterior horn disease
2. Bulbar palsy (arteriosclerotic)
3. Pseudobulbar palsy
4. Basilar artery thrombosis
5. Vascular anomaly (aneurysm of basilar artery)
6. Tumor (pontine)
7. Hyperparathyroidism
8. Myasthenia gravis
9. Guillian-Barre's syndrome
10. Bulbar multiple sclerosis
11. Multiple CNS metastases
12. Toxic encephalitis (CO, As, etc.)

All of these conditions may produce bulbar signs. In the process of elimination, the negative spinal fluid findings rule out poliomyelitis, or encephalitis or other anterior horn-cell disease not already ruled out by the history. The absence of fibrillation and vacillation of the clinical course are not characteristics of bulbar palsy. Basilar artery thrombosis causes quadriplegia and death in about twenty-four hours, if complete; if incomplete, I would expect more neurological signs as a result of brain stem and cranial nerve nuclear involvement; the same arguments apply to aneurysms. Pontine tumors are rare at this age; furthermore, the patient had no headaches, dizziness or visual disturbance. Hyperparathyroidism must be considered, especially with the long history of bone aches, demineralization and leg weakness; the x-rays show no cystic changes, but these are not invariably present. Guillian-Barre's disease is a diagnosis which, if made at all, should be considered only in a patient with a fairly characteristic picture. The patient's age is the biggest argument against multiple sclerosis, although this disease could begin at this age. I would expect more neurological findings in the extremities, however; furthermore, even apoplectic onsets of multiple sclerosis usually produce a history of previous symptoms upon specific questioning. There is nothing to suggest a primary tumor, and multiple metastases would not have produced such a fluctuating clinical picture. No exposure to a toxin makes toxic encephalitis untenable as well as lack of more widespread evidence of brain involvement.

Myasthenia gravis and pseudobulbar palsy must be considered seriously. There is a past history of hypertension; therefore, vascular disease is possible. There is no atrophy; pyramidal tract involvement is common in pseudobulbar palsy, absent in this case. Past history of a stroke is also common, again lacking here.

Myasthenia gravis may appear in older people. The clinical vacillation in severity of symptoms is quite consistent with this diagnosis. Respiratory muscle weakness is common in myasthenia gravis. Clinically, myasthenia gravis usually falls into three groups: (a) bulbar, (b) ocular, (c) myasthenia of the extremities. This case was primarily bulbar in type with minimal ocular signs. Of course, most cases are much more gradual in their onset than was this case, but such sudden onsets occur and may be an exacerbation of a subclinical form of the disease. Unfortunately, we have no therapeutic test (prostigmine) recorded in this case. I believe this patient died of an acute form of myasthenia gravis but cannot definitely rule out pseudobulbar palsy. The other possibilities are improbable for the reasons mentioned above.

Dr. I. T. Clark: The chest x-ray shows high diaphragms and right lower lobe atalectasis. No evidence of thymoma is seen.

Doctor Gowan's Diagnosis

1. Myasthenia gravis
2. Possible pseudobulbar palsy

Anatomic Diagnosis

1. Benign Thymoma
2. Acute myasthenia gravis

Dr. A. C. Aufderheide: The heart weighed 380 grams. It was otherwise normal; except for lower lobe atelectasis on both sides, the lungs were not abnormal. The gastrointestinal tract showed no pathologic lesion. A small benign fibroma was present in the right ovary. A benign cortical adenoma (3 cm. in diameter) was found in the right adrenal gland. Osteoporosis of the lumbar vertebrae was apparent. Four parathyroids were grossly and microscopically normal. The parenchymal and vascular tissue of the brain and spinal cord showed no gross or microscopic changes. Microscopically, the skeletal muscle of the diaphragm was not abnormal. Situated in the superior anterior mediastium in the region of the thymus gland was an encapsulated, lobulated, hard tumor measuring 4 x 3 x 3.5 cm., which on cut section was white, trabeculated with a few hemorrhagic areas. Microscopically, the tumor consisted of larger epithelial-appearing cells mixed with smaller cells indistinguishable from lymphocytes (Fig. 1). The picture is that of a benign thymoma.

The absence of central nervous system lesions, the presence of a benign thymoma and the clinical history led us to conclude that this was a case of acute myasthenia gravis.

Discussion

Dr. H. Fisketti: Are malignant tumors of the thymus ever associated with myasthenia gravis?

Dr. A. C. Aufderheide: Rarely, a few cases have been reported, but with these few exceptions, thymomas accompanying myasthenia gravis are benign.

Dr. A. C. Aufderheide: About 50 per cent of myasthenic patients have a thymoma or hyperplasia of the thymus on x-ray examination.

Dr. J. Coll: Johns Hopkins University has reported up to 80 per cent at autopsy, if a careful search is made.

Intern: What is the current status of thymectomy in myasthenia gravis?

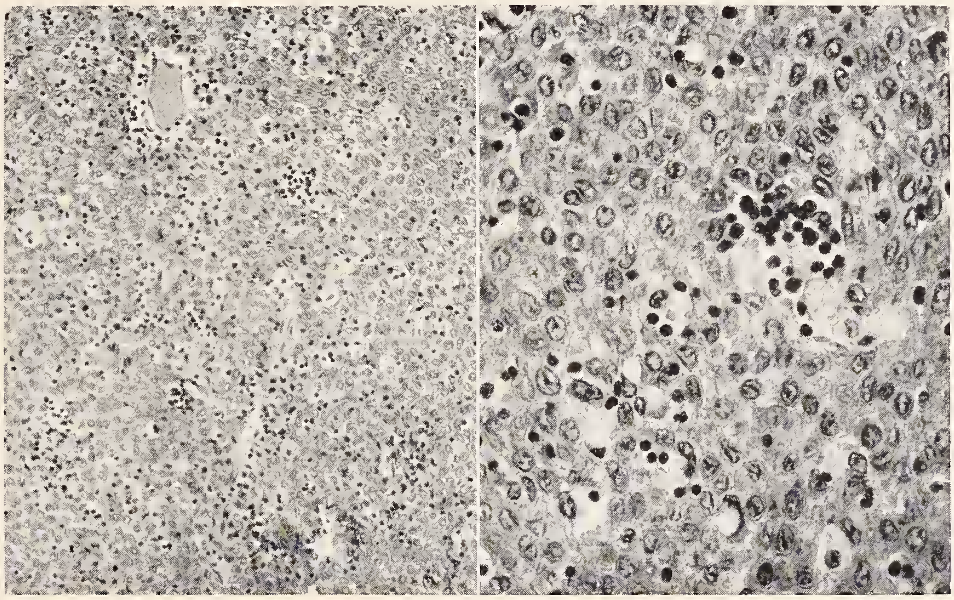

Fig. 1. (A) Low power photomicrograph of the thymic tumor. Note the cellularity. (B) High power photomicrograph of the thymic tumor showing the two types of cells. The smaller, dark-staining cells resemble lymphocytes while the others are much larger and stain less deeply.

Dr. J. K. Butler: What is the treatment of choice?

Dr. J. B. Moyer: Neostigmine tablets are the most popular; the methyl sulphate form of neostigmine is available in ampule form for emergencies. Other products are also available; I haven't had much experience with them but I understand they are quite toxic. It is important that *enough* drug be given; too many myasthenic patients are undertreated by their physician.

Dr. N. E. A. Leppo: What is the incidence of thymoma in myasthenia gravis?

Dr. Gowan: Debatable at present. The Lahey Clinic staff feels that their series shows definite benefit from thymectomy; the Mayo Clinic staff felt otherwise but recently supported the eastern school after re-evaluating their results. Thymectomy usually produces a severe postoperative transient exacerbation of the disease so that treatment must be vigorous during that phase.

I think this patient had had subclinical myasthenia gravis which probably caused enough muscle weakness to result in her frequent falls and that the present episode represents an acute exacerbation of the disease.

POSTOPERATIVE WALKING

Although having surgical patients ambulate soon after their operation has been widely practiced since World War II, Palumbo believes it should be followed even more extensively than it is today. He feels that hesitancy on the part of many surgeons is due to fears that certain undesirable effects such as wound disruption may occur. The author disagrees and notes that "Through disturbances in metabolism, prolonged bed rest produces weakness and loss of tone of both smooth and skeletal muscles, loss of calcium and nitrogen from the body, reduced vital capacity, decreased cardiac output, slowing of circulation, and a delay in wound healing. These changes may result in an increased incidence of complications of the gastrointestinal tract, as evidenced by ileus, constipation, nausea, vomiting, and/or decrease or loss of appetite." Conversely, "Early ambulation enhances wound healing and reduces other complications which may occur in the gastrointestinal tract, in the cardiopulmonary and in the peripheral-vascular system." —Palumbo, L. T.: Early postsurgical ambulation, *Journal of the Iowa State Medical Society,* 45:12 (Jan.) 1955.

President's Letter

IN APPRECIATION

This issue of Minnesota Medicine should reach you about the time of the state meeting, and the impact of the work of your state association, plus the work of your local arrangements committees in bringing to you this excellent annual meeting, should be fresh in your mind.

On occasion, I have been asked by members of local units of medical societies, "What does my county medical society do for me?" At such times, even though I could talk indefinitely on the subject, I have often felt completely tongue-tied and frustrated. Perhaps I have felt somewhat as you would feel if, after you had successfully seen a patient through a critical illness, he were to say to you, "I guess I would have done just as well if I had gone to bed and seen it through without you, eh, Doctor?"

That the physician can ask such a question about his medical society, is evidence that he is not even a member of the society in his own heart. If he had helped to cook the meal, he would inevitably have tasted some of the bounties of society membership in the process.

So many members have participated in the work of our state association that to single out any one man or group would be an injustice. The work of the Hennepin County Medical Society, our hosts at the state meeting; the Insurance Liaison Committee; the Committee on Malpractice; the committee studying our functions in civil defense; Maternal and Child Health Committees; and the editing, publishing, and editorial boards of Minnesota Medicine, to name only a few, have been so outstanding that our membership owes them a debt of gratitude beyond their ability to repay.

It is, indeed, a source of satisfaction to your officers and Council that when help and advice is needed, it is freely given. Time and efforts seem of little consequence to these devoted members of our Association when they are asked to contribute to the profession of our state.

In the light of the accomplishments of the committees, on both scientific and non-scientific work, can any one of our members seriously ask, "What does my society do for me?" Rather let us ask, "How can I aid in the dedicated work of our Association, whose object is the improvement of public health, the advancement and dissemination of scientific knowledge, and the protection and advancement of our profession in the accomplishment of these objectives?"

Arnold O. Swenson

GENERAL PRACTICE SYMPOSIUM

This number of Minnesota Medicine contains material presented on October 20, 1954, at the Fourth Annual Refresher Course of the Minnesota Academy of General Practice in Rochester.

This meeting was representative of what I feel to be one of the richest heritages of American medicine. Five hundred general practitioners registered and attended the meetings wherein fourteen specialists gave of their time and knowledge. The meeting demonstrated a co-operation for the good of the patient that is typical of the medical profession. Nothing could so well belie those vocal few who would have us believe that the specialist and the general practitioner are continually at each other's throat. The attendance and attention of the general practitioners earned them the respect of the speakers.

Members of the Minnesota Academy of General Practice have seen these meetings grow and have watched the enthusiasm mount each year. This annual meeting, along with the regional meetings that are held throughout the state, gives general practitioners an opportunity to get postgraduate instruction that will qualify them for continued membership in the Academy. It also provides nonmembers with an opportunity to "refresh" themselves.

The papers included in this symposium are not meant to be a basic contribution to the medical literature but do review some of the basic considerations in diagnosis and treatment of the conditions discussed. It is considered that their inclusion in Minnesota Medicine might be of value to physicians unable to attend the meeting.

H. A. Wente, M.D., *Secretary-Treasurer*
Minnesota Academy of General Practice

BMD

The last twenty-five years have flooded us with alphabetic agencies, and he is indeed a dolt who doesn't understand UN, WHO, UNESCO, et cetera. The Armed Forces gave us a goodly number of useful alphabetics; e.g., SOP for Standard Operating Procedure (quite reminiscent of the s.o.b. that appears on clinical histories to indicate short of breath—beware of capitalizing these letters, though), and SNAFU for Situation Normal, All Fouled Up. The tendency to reduce communications to a series of letters has even carried into domestic life. We know an efficient head-of-a-family who used to telephone home just as he left his office to deliver the command, "PMC," and the wheels would begin to turn at home in anticipation of his arrival. This worked fine as long as he drank only coffee, because even his youngest child could comprehend this cryptic command, "Pour My Coffee." As he rose in the world, his tastes became more expansive and expensive, and an alternate translation appeared, "Pour My Cocktail(s)." Finally, when he went on a reducing diet and "Peel My Carrots" was added to the reasonable interpretations, things became so chaotic that he had to revert to imperative sentences rather than initials—like ordinary inefficient folks. Thus ends one success story.

Now this BMD business, which insidiously entered our lives via an innocent conversation, has to do with success in another way. It is a criterion of success. You remember how in order to pick the man-most-likely-to-succeed in our class, we first strove for a definition of success. We settled for health, wealth and happiness, without thinking that we still had not arrived at an objective definition. In any event, many of us were sure that we were successful when we could go around with roseate cheeks, a smiling face, and a new Buick for house calls. This rotund, bourgeois concept of success was soon elbowed out by the unsettling information that a man was successful only when he had the prerogative of choosing the interior decorator who would do his office—at least junior partnership in the firm.

Now this BMD came to us as a subheading of the interior decorative criteria of success when a friend of ours declared he was working for his BMD. We were unable to equate this with any degrees we'd heard of and were wondering whether it had to do with a new telescoped type of Bachelor-Doctor of Medicine when he gave us the literal translation: Big Mahogany Desk.

H. G. M.

SPECIALTY TRAINING IN ALLERGY

Allergy must now be considered as a clinical entity with its various phases integrated by known factors or implications. It is a specialty which must be correlated with all other specialties of medicine. There is a growing appreciation that allergy is wholly or partially responsible for so many diseases or symptom-complexes that it is expected to be met in the practice of the internist, pediatrician, dermatologist, otorhinolaryngologist, and general practitioner. They cannot escape from the responsibility of at least its recognition so that the patient may be referred to a properly trained allergist or they must become trained in the specialty themselves.

The primary allergic diseases, asthma and hay fever, afflict approximately 10 per cent of the total population, making this category of chronic diseases third in prevalence in the United States. We must also recognize that the mechanism of hypersensitivity is responsible for plant dermatitis, urticaria, eczema, allergic headache, allergic evidence of infectious diseases, rheumatic fever, serum sickness and drug allergies, thus making the incidence of allergy much higher.

Allergy in industry is becoming a serious problem, and many manufactured products now cause important allergic diseases. Allergic reactions to our modern drugs, particularly to antibiotics, are mounting to alarming proportions and becoming a very serious problem. Allergy today is a social problem, extending from birth to old age.

Certification, in itself, in internal medicine and pediatrics does not indicate that a physician is qualified for the diagnosis and treatment of allergic disease. The extremely small number of physicians subcertified in allergy attests to this. There are only seventeen AMA-approved institutions in the United States which train residents and fellows in allergy. A well-organized American Foundation for Allergic Diseases is now carrying on these functions of teaching and research. The impact of allergy on medicine must be strengthened by the education of physicians and the public alike.

Fred W. Wittich, M.D.

FARM PRICES

The medical profession should be very familiar with the American concept of profitable production; namely, that the units of production multiplied by the price per unit produced, less the cost to produce, means the eventual profit.

Farmers, like doctors, live and progress on profits. They do not live off just price or production. Farm production is subject to the vagaries of the weather, varies from year to year and from locality to locality. Farm prices should be allowed to flex in line with needed production, in order to keep down price depressing surpluses on the one hand and to stimulate needed production on the other hand. This is the basic concept of our free enterprise system.

Since in the late 1930's, the government has been trying artificially to peg prices to farmers in order to insure a measure of farm stability. In times of full farm production and reasonable costs, artificially pegged high farm prices bring high prosperity to farmers. On the other hand, if artificially pegged high prices create surpluses which force production cuts and higher costs, the farmers actually receive less net income. This is what has happened in agriculture within the last several years.

Cotton producers and tobacco producers voted and accepted high government prices and took acreage cuts in return. These cut-out acres went into wheat, corn and feed which in some cases were also price-supported too high, and the results were surplus produce and acreage cuts.

Today, we are witnessing the confusion of government interference in agriculture. Some commodities are artificially high priced above market demand and are causing ceiling prices and restrictions. Other commodities are supported flexibily and are feeling the effects of the spill-over of acreage cuts of high supported crops. Feeders and dairymen are feeling the effects of governmentally determined high feed costs, while their products are allowed to drop. Butter must drop because it is too high for its competition or continue to loose its market. If the socializers and communizers wanted to create confusion in agriculture, they couldn't have done a better job. Or maybe the boys that wrote and policed the bills did know what they wanted to do.

I hope physicians won't buy such government paternalism. Perhaps we can all work together to get back to the real system.

J. Delbert Wells, *Secretary*
Minnesota Farm Bureau Federation

LOSS OF HEARING IN CHILDREN

Loss of hearing in children is of two main types: (1) middle-ear dysfunction, which is often preventable, and (2) nerve dysfunction, for which no prevention or cure exists at present.

The Committee on Conservation of Hearing of the Minnesota State Medical Association conducted a survey of school children in the state. As a result, 1,028 children were reported to have loss of hearing sufficient to be a handicap in school and later life. Only 175 of these were under treatment or in special schools.

The committee prepared a brochure that has been mailed to all physicians in Minnesota. This brochure presents a concise digest of present opinion in the fields of treatment for loss of hearing, training of the deaf child and selection of a hearing aid. It should be filed in an available location by all physicians.

The Minnesota Department of Health is co-operating in the project by mailing letters to the parents of children discovered by the survey. Parents are advised to seek medical advice for diagnosis and for therapy or rehabilitation of the handicapped child.

This program demonstrates the close co-operation between organized medicine and public health agencies. Further co-operation by individual physicians is required to carry the project to a successful conclusion. With the information provided, every physician can give valuable advice to the parents of children handicapped with respect to hearing.

K. M. Simonton, M.D.

DIABETES DETECTION PROGRAMS

It is axiomatic that the earlier the diagnosis of an ailment, the better the prognosis for greater comfort, for prolongation of life and for cures. It is unfortunate that in some diseases, such as cancer, a diagnosis is quite impossible until the condition is fairly well advanced. Diabetes is one disease in which a correct diagnosis can be made quite simply. It can be suspected without the patient's even visiting the doctor, by having the urine examined for sugar. If glycosuria is present, then more careful tests can be made to establish definitely the presence or absence of the disease. Because of this simplicity for mass detection, diabetes detection drives have been instituted all over the country. Through this procedure, a possible one million diabetic persons might be found and placed under proper supervision and control.

The more recent introduction of the St. Louis Dreypak strip has simplified the entire procedure. The strips, after having been immersed in the urine and dried, can be sent through the mail to the laboratory with practically no inconvenience to the patient. Every community should arrange for the simple facilities necessary to carry out this procedure. From this center, the results may be transmitted to the patients. Such an arrangement should prove very simple and inexpensive. The co-operation of the medical profession in the Diabetes Detection Week conducted by the American Diabetes Association will help establish excellent public relations between the medical profession and the community.

In the Diabetic Detection Drive in Minneapolis in November, 1952, 32,063 specimens were examined, of which 657 (about 2 per cent) were found to be positive for sugar. Of these persons, further tests proved that 40 per cent were truly diabetic, and they were advised to consult their doctors for management and control.

Moses Barron, M.D.
Governor, Minnesota District
American Diabetes Association

HOW LONG SHOULD ONE KEEP VALUABLE PAPERS?

These days all of you have to contend with the problem of deciding how long records and other valuable documents should be retained. You are concerned with keeping not only those records, documents and papers necessary for the protection of your interests in the ordinary administration of living but also those which are necessary as a result of your professional practice.

Quite apart from the maintenance of files with respect to the treatment of patients, as to which you may have some kind of moral obligation, there is the possibility that at a future date you may be called upon in a proceeding in court or elsewhere to present your records for the purpose of verifying and establishing what has or has not been done. It is impossible to enumerate all of the instances in which a physician's records may be required. There may be occasions where it will be of value for you to use records merely to refresh your recollection as to whether you were in or out of the city on a particular date. It is quite possible that at some time you will be called upon to explain and even justify the method of treatment employed in a particular instance. Almost surely, you will be called upon at some time to explain the extent and nature of your income and of your deductions for income tax purposes.

As a rule of thumb, it seems desirable that account books and all other records reflecting income and expenditures should be kept until January first of the eighth year after the year to which they pertain. If a creditor attempts within that time to assert that a bill has not been paid, you will have your records available to dispute him. Or if the tax collector has some question as to the proper tax liability for a given year, the correct data will be available for his perusal and for use in court, if necessary.

Deeds, mortgages, leases and other documents pertaining to real estate are seldom of burdensome volume and should be retained indefinitely. A minimum tax file should be kept for an indefinite period. This should contain not only the returns but also sufficient supporting evidence to establish your income and your deductions. Papers having no particular present interest may be destroyed when their usefulness has been served. In this class fall expired policies of insurance where no loss has occurred (other than liability insurance), cancelled savings account books, contracts which have been fully performed, and similar documents. As to checks and records pertaining to items which do not have tax consequences, the eight-year period seems to present only reasonable risks, if any.

Of course, in any unusual situation, you will want to consult your lawyer because of the obvious danger that the general rule may not cover the particular situation.

Roland J. Faricy, *Attorney*
Saint Paul, Minnesota

TONGUE CANCER TREATMENT

Initial treatment of the primary lesion in cancer of the tongue and floor of the mouth seems to be best accomplished by radiation therapy, Dr. C. L. Ash, of Toronto, Canada, has concluded.

Dr. Ash presented his conclusions, based on a five-year study of thirty-nine patients with cancer of the tongue and ninety-five patients with cancer of the mouth floor, in a recent (April, 1955) issue of the *American Journal of Roentgenology, Radium Therapy and Nuclear Medicine.*

The Canadian radiation specialist is associated with the Ontario Institute of Radiotherapy and the Department of Radiotherapy in the Toronto General Hospital.

"In general, the secondary lesions of the oral cavity developing in the lymph nodes of the neck are most adequately treated by radical surgery," Dr. Ash said.

He admitted, however, there are certain exceptions to this rule.

"The patients we treated represent all the various forms of radiation therapy—radium in the form of molds, needles, radon seeds, teleradium therapy, or roentgen rays of 200 to 400 kv., as well as intraoral roentgen rays generated at 88 to 200 kv."

His overall results showed a 49.9 per cent "control"—that is, a total of five years with the lesion healed—for cancer of the tongue and 38.7 per cent control in cancer of the mouth floor.

However, in the early cases of tongue cancer, there was 67.0 per cent control—as compared with 32.3 per cent control among the late cases.

In mouth-floor cancer, there was 49 per cent control in the early group and 26.2 per cent in the late.

"Better results appear to attend the use of radium, or a combination of interstitial radium and roentgen rays, than is the case when external therapy is used alone," Dr. Ash said. His conclusion:

Studies at present are being made as to the value of extending the field of surgery in the so-called radiation "failures"—particularly when initial treatment has failed and the lesions remain localized.

AIR CONDITIONING

The wide differential in temperature between summer climates and some air-conditioned interiors poses a possible health question. "The chief difficulty centers about the 'comings and goings' of occupants of this artificial climate." In winter, the human body becomes adjusted so that persons leaving interiors heated to about 80 degrees (Fahrenheit) can enter a near-zero environment with only the addition of an overcoat and hat. In summer, however, moving from air-conditioned environments with relatively low temperatures into exteriors of high temperatures may result in a condition of "thermal shock." The ideal solution of a three to four stage transition is unfortunately impractical. "Under the circumstances described, much may be accomplished by clothing adjustments. In many air-conditioned spaces, particularly if there is excessive air motion, added garments are necessary, especially among women. The divestment of these garments aids the physiological state on re-entering the hot outer air. Humidification of the air is less important to health than was earlier contended. As to comfort, the degree of humidity may be more important but still is not fundamental. Some investigators, with respect to air conditioning in summer, advise merely dehumidifying the air to a low point without effort to lower temperatures, but this may give rise to an unpleasant sense of chilling owing to increased evaporation. In any event, a humidity between 40 and 60 per cent is regarded with favor."—Queries and Minor Notes: Air conditioning, *Journal of the American Medical Association* (157:1265 (April 2) 1955.

Medical Economics

Edited by the
Committee on Medical Economics,
Minnesota State Medical Association
George Earl, M.D., Chairman

AMA REVIEWS LEGISLATION STATUS

After three months of the 84th Congress, the American Medical Association has published a summary of the status of federal legislation of interest to the medical profession. More than 200 medical-interest bills are being followed by the Washington Office of the AMA, and also considered are pertinent testimony before committees, committee actions, and all available information on future plans and objectives of the Administration and Congress. An early April issue of an AMA Washington Office Special Report reviews current status of legislation under several categories:

Reinsurance

Legislation provides an initial $25 million to start a trust fund that would be maintained by percentage payments from premiums of participating health insurance plans. The fund would reimburse voluntary health insurance plans (commercial and nonprofit) for abnormal losses in extending coverage and expanding benefits. This is on the "must list" of the Administration's health and medical care program. No hearings had yet been scheduled in early April.

According to the Report:

> "While endorsing the stated purposes of the bills (to promote the best possible medical care on reasonable terms), the American Medical Association again opposes the proposal on the grounds that (1) extensive private funds are available within the insurance industry for such purposes, (2) reinsurance doesn't provide a means for making insurable what otherwise would be an uninsurable risk, (3) it will not fulfill its intended purpose and might even inhibit the satisfactory progress made to date by voluntary plans, and (4) it is a potential subsidy."

Mortgage Guarantee

For a fee, this legislation would guarantee up to 95% of private mortgages for construction of non-government health facilities, to be owned and operated for profit or on non-profit basis. The mortgage could not exceed 80 per cent of the estimated value of the project and equipment, and maturity could not exceed thirty years. The guarantee would apply to refinancing, as well as to new construction and modernization. Hearings are to be scheduled.

The AMA Report states:

> "The Association (AMA) is actively opposed to this legislation on grounds that (a) private financing is meeting the need, and (b) the proposal represents intrusion by the federal government into a field where government help is not required."

Mental Health

The Administration wants a new five-year program of increased grants to states on a need-population-per-capita-income formula to help maintain and improve mental health facilities, to stimulate special projects, and to train more personnel. Several bills for grants to finance a three-year survey have been introduced, and another to create a permanent federal commission on mental health, which would study the problem, make recommendations and attempt to co-ordinate all work in this field, private as well as government. These proposals have made the most progress of all health bills, and the former, both in the House and Senate, are expected to reach the floor.

AMA policy on this matter is: wholehearted support of the survey bill, also favoring the Administration bill, but only as a temporary measure until Congress has been able to redefine the federal and local areas of responsibility in public health matters. The Report states: "This interest in mental health problems dates back to the founding of the AMA more than a century ago."

Federal Aid to Medical Education

Plans for federal aid to medical education range from "one-shot" construction grants to outright operating aid for schools increasing enrollment. Most prominent in this Congress are identical bills in the House and Senate, providing a five-year $250 million program of construction, expansion, modernization, and maintenance grants to new and existing schools. Hearings should be scheduled shortly.

According to the Special Report:

> "The Association favors one-time construction, renovating and equipment grants to medical schools on a matching basis similar to the Hill-Burton formula, but opposes federal grants for instruction or continuing grants for operation or maintenance. It approves the Hill-Priest bill, providing some specific changes are made in line with the above policy. It opposes the Burnside bill, until he accepts changes that have been suggested to him."

Doctor Draft and Military Medical Scholarships

The Doctor Draft extension bill would continue the present act for another two years beyond July 1, 1955. Under the scholarship bill, the government would pay up to $133 a month, plus tuition and fees. Students would be obligated for three years' active duty if the scholarship was for a year or less, and four years if for more than one year.

The Doctor Draft provision is expected to come up this session, but hearings had not been scheduled in early April. The scholarship bill is an official Administration measure, and is planned for consideration before the Doctor Draft act.

The AMA policy on the above is described as follows:

> "When there was a proven need for it at the start of the Korean War in 1950, the Doctor Draft was supported by the AMA. The AMA also supported one extension of the law. Now, in the face of the Defense Department's request for another (and peacetime) extension, the AMA's policy is unchanged. If it can be demonstrated that there is a continuing need for the act, the AMA will support the extension. Evidence so far presented has not established the need. The Defense Department admits the regular draft obligation will supply it with the young physicians it needs, but says that the Doctor Draft is required to bring in more experienced men with special skills and administrative ability. Without these, the Department insists, the military medical services cannot be maintained during the next two years. The AMA believes the services could do a great deal more to build up their regular Medical Corps and to make more efficient use of the experienced men now in uniform."

Regarding the military scholarships, the AMA supports the scholarship idea, provided that (1) a student not be approached by the military until he is fully matriculated in the medical school, (2) no student so selected receive any preferential treatment, and (3) number of military scholarships in a school not exceed 5 per cent of any year's class or the total enrollment.

Military Dependents

The present program of medical care for military dependents is irregular. Legislation would substitute a plan that would (a) apply a uniform definition of dependents to all services, (b) make all dependents eligible for the same amount of treatment, and (c) offer relatively the same degree of care regardless of residence of the dependents. Uniformed physicians and military hospitals would take care of all dependent patients within limitation of resources. The Secretary of Defense could set a token fee schedule to be charged dependents in military facilities.

No hearings had been scheduled at the release of the AMA Special Report. Two identical bills have been introduced in the House and Senate, and it is felt that the Administration will support some kind of change in the present law.

The AMA has no argument with the military services on most provisions of the Defense Department bill, but is unalterably opposed to one part of it: "Whereas the Administration thinks the military medical departments should care for all the dependents they can handle, the AMA feels that dependents, like other civilians, should be treated by private physicians and in private hospitals unless these private facilities are inadequate. In the latter case it would be the military's responsibility to care for dependents." The AMA is working on a set of guiding principles to propose for amendment when the bill is brought up.

TAX DEFERMENT BILLS MAKE SLOW PROGRESS

There seems to be little evidence that Congress will act on the Jenkins-Keogh-Ray type of bills this session. The Treasury Department has studied some of the proposals, but the Administration is not supporting any.

The purpose of the Jenkins-Keogh and Ray bills is broadly the same: "namely," according to a recent issue of the AMA *Journal,* "to encourage but not compel saving for retirement by the self-employed and by employed persons whose employers have not established pension and/or profit-sharing plans for them . . . Both bills make special provisions—past service credits—for those older self-employed and pensionless employed persons who have not had the benefit of tax deferment during the early and middle parts of their working lifetimes."

The American Medical Association supports all these bills, including medical expense deduction bills, but among the tax deferment proposals it prefers the Jenkins-Keogh approach.

NATIONAL BOARD NOTES EXAM REQUIREMENTS

The National Board of Medical Examiners has released general information on taking national board examinations, which should be of value to many physicians. The National Board is a voluntary and unofficial examining agency, the purpose of which is to "prepare and to administer qualifying examinations of such high quality that legal agencies governing the practice of medicine within each state may at their discretion grant successful candidates a license without further examination," their publication states.

The National Board certificate is accepted as a suitable qualification for the practice of medicine by forty-one licensing authorities in the states, the District of Columbia, Hawaii and Puerto Rico. Minnesota is one of these states.

The examinations are divided into three separate parts, I, II and III which must be taken and completed in numerical sequence. Examinations are held in February and June at medical schools in the U. S. and Canada; an additional examination in Part II is held in April and an additional examination in Part I in September.

Who Is Eligible?

The National Board admits to its examinations any student in or graduate of approved medical schools in the United States and Canada. A candidate is eligible for Part I when he has completed the first two years of work in an approved medical school; eligibility for Part II calls for successful completion of a four-year medical course in an approved medical school; a candidate is eligible for Part III if he has passed Parts I and II, received a degree of doctor of medicine, and served at least one year in an approved hospital internship.

Advantages Named

In its recent publication, the National Board examination advantages are outlined as:

> "Because the answer sheets are machine scorable, the grading can be accomplished rapidly, accurately, and impartially. With this type of examination, it becomes possible to determine the level of difficulty of each test and to maintain comparability of examination scores from test to test and from year to year for any single subject. Moreover, of even greater long-range significance is the facility with which the total test and individual questions can be subjected to thorough and rapid statistical analyses, thus providing a sound basis for comparative studies and for continuing improvement in the quality of the test itself."

Further advantages result from the fact that these examinations are set up in three parts, the Board states, and may be taken during the course of training in the medical school when the student is fresh from his preparation in the various subjects included in the medical curriculum.

Preparation of Examinations Noted

The summary of examinations by the National Board publication states that approximately a year goes into the preparation of each examination. Each committee member thoughtfully and laboriously writes test questions selecting that type best suited to a particular point. Each question is then subjected to the critical review of the other members of the committee; any doubtful item is revised or discarded. It concludes: "Hence, each examination contains only material that has been thoroughly worked over and agreed upon as appropriate, free from ambiguity and representative not only of important aspects of a subject, but also of high standards of medical education."

In 1902, Charles Richet, a French physician, theorized that an inoculation of a given protein in animals would produce a hypersensitivity to that protein. He termed this process "anaphylaxis," derived from the Greek *ana,* meaning "backward," and *phylaxis,* meaning "protection." The term, then, refers to the reverse of "prophylaxis," or a state of increased susceptibility to a drug protein or toxin following administration of the drug.—Wain, H.: The story behind the word, *Ohio State Medical Journal* 51:362 (April) 1955.

Current Concepts

IATROGENIC HEART DISEASE

CHARLES N. HENSEL, M.D.
Saint Paul, Minnesota

The word "iatrogenic" comes from two Greek words meaning "physician and producing"—actually generated by the physician. It is a term applied to disorders induced in the patient by autosuggestion, resulting from the manner in which the physician conducts his examination, and what he tells the patient.

Today, when there appears to be such a great increase in the incidence of coronary arteriosclerosis with coronary occlusion and myocardial infarction, everyone is aware of this growing menace to life and health.

Consequently, more than ever before, people with any pain or abnormal feeling in the left chest seek medical advice to learn how serious this symptom may be. If the doctor, after a brief history and physical examination, finds a regular heart of normal size and a normal blood pressure. and tells the patient, "I find nothing wrong, but you'd better be careful at your age," or, "I find nothing wrong, but you'd better take a little digitalis and avoid doing anything strenuous," then he is is likely to generate "iatrogenic heart disease."

Actually, when a doctor gives such advice, he is "straddling." He is not entirely sure himself. and so, should this patient later develop actual organic heart disease, he wants to be able to say, "You see I was right. I warned you."

When any person first comes to a physician complaining of a pain or an ache in his left chest that physician is charged with a very grave responsibility for making the right diagnosis and for telling the patient, at once, he has or he does not have heart disease.

The first contact with such a patient is most important, because how the doctor conducts himself may determine success or failure in handling the case. He must sit quietly with the patient and take plenty of time to obtain a complete history of his chest pain or ache. When did it begin—day or night? What was its relation to exertion, to rest, to anxiety? Was there any antecedent exhausting illness? Was there a recent bereavement, or grief over the death of a loved one? If such a death were sudden and from a heart attack, does this patient fear that he, too, may be so stricken?

Has there been a series of strains and anxieties in the mother of a large family, with many illnesses and many nights of broken sleep? Has there been a recent "bout" of upper respiratory tract infection or a tonsillitis or a pleurisy?

Inquiry into all of these factors will point toward the diagnosis of either organic heart disease or a functional heart disturbance, such as a nervous heart.

The next step is a complete physical examination with clothes removed. This should include pupillary reactions, examination of the oral cavity, palpation of the thyroid gland, examination of the lungs, determination of the heart borders and auscultation of the heart, determination of blood pressure, examination of the abdomen, rectal examination, study of the reflexes, a check for edema of the shins, temperature of the body, and examination of urine and blood.

Next follows the examination of the heart after exercise, using such a simple test as twenty hops on one foot and twenty hops on the other foot. noting the height of the pulse and the blood pressure and the time of their return to normal.

Then, and not till then, comes the observation of the heart and lungs under the fluoroscope, study of the heart silhouette from a 6-foot heart film, and reading of the electrocardiogram.

If all of these examinations and tests have produced normal responses, then and only then, can the examining physician be justified in telling the patient that he does not have any heart disease at all, that the dull ache in his left chest and the palpitation of his heart when he gets into bed at night are "fear reactions," because fear tends to pour extra adrenalin into the blood stream, and it is this extra adrenalin that makes his heart slam and bang against his ribs.

Tell him that the symptoms of organic heart disease are relieved by the horizontal position. that the pain of organic heart disease is not a dull ache, but a sharp stabbing pain, which passes with rest or standing still.

Tell him that a dull ache in the left chest is frequent in people with a nervous heart.

Look for other associated nervous signs, such as light headedness, trembling, sweating and an abnormal tendency to sigh.

Tell him that exercise is good for people with nervous hearts and that they should walk erect and breath deeply.

Do not ever hedge—tell him yes or no. And if he has no organic heart disease, tell him to do normal things and to lead a normal life. But whatever you tell him, be definite.

Reports and Announcements

MEDICAL MEETINGS

State

MINNESOTA STATE MEDICAL ASSOCIATION, annual meeting, Minneapolis, May 23-25, 1955.

Minnesota Academy of Occupational Medicine and Surgery, annual meeting, Minneapolis Athletic Club, May 25, 1955.

American Medical Association, annual meeting, Atlantic City, New Jersey, June 6-10, 1955.

American Proctologic Society, annual meeting, Hotel Statler, New York, New York, June 1-4, 1955.

International

International College of Surgeons, twentieth anniversary congress, Palais Du Conseil General, Geneva, Switzerland, May 23-26, 1955.

International Hospital Congress, Lucerne, Switzerland, May 30-June 3, 1955.

International College of Surgeons, Cape Cod regional meeting, Chatham Bars Inn, Chatham, Massachusetts, July 1-4, 1955.

International Symposium on Enzymes: Units of Biological Structure and Function, Henry Ford Hospital, Detroit, Michigan, November 1-3, 1955.

AMERICAN ACADEMY OF GENERAL PRACTICE

The American Academy of General Practice is allowing twenty hours of informal credit to its members who attend the medical sessions of the annual meeting of the National Tuberculosis Association and its medical section, the American Trudeau Society. The sessions will be held in Milwaukee, Wisconsin, May 22 through 27.

Further information may be obtained from the Minnesota Tuberculosis and Health Association, 614 Portland Avenue, St. Paul, Minnesota.

AMERICAN ASSOCIATION OF ANATOMISTS

At the sixty-eighth annual session of the American Association of Anatomists, held at the Jefferson Medical College, Philadelphia, April 6 through 8, Dr. Edward A. Boyden, University of Minnesota professor emeritus of anatomy, was named president-elect of the organization. He will take office in April, 1956.

Dr. Boyden, who retired as head of the University of Minnesota's anatomy department in 1954, is currently a visiting professor of anatomy at the University of Washington, Seattle.

MINNESOTA CHAPTER, ARTHRITIS AND RHEUMATISM FOUNDATION

The formation of the Minnesota Chapter of the Arthritis and Rheumatism Foundation was completed in Minneapolis on April 13 with acceptance of a charter from the national foundation. Elected as officers of the organization were Dr. Charles Slocumb, Rochester, president; Dr. Macnider Wetherby, Minneapolis, first vice president, and Dr. Cecil J. Watson, University of Minnesota Medical School, second vice president.

Executive secretary of the chapter is R. V. Stevenson, with offices at 89 South Tenth Street, Minneapolis.

Purpose of the foundation is to fight arthritis and rheumatism by working for establishment of free clinics for treatment and to provide for research through establishment of scholarship and laboratory grants.

ST. LOUIS COUNTY SOCIETY

The St. Louis County Medical Society held a meeting at St. Luke's Hospital, Duluth, on April 14. Principal speakers at the meeting were Dr. William B. Martin and Dr. Kenneth A. Storsteen, both of Duluth. They discussed the diagnosis and treatment of hyperthyroidism, using radioactive substances.

MINNESOTA OBSTETRICAL AND GYNECOLOGICAL SOCIETY

Recently elected as officers of the Minnesota Obstetrical and Gynecological Society were Dr. Leonard A. Lang, Minneapolis, president; Dr. Rodney F. Sturley, St. Paul, vice president, and Dr. Edward A. Banner, Rochester, secretary-treasurer.

MINNESOTA SOCIETY OF NEUROLOGY AND PSYCHIATRY

The Minnesota Society of Neurology and Psychiatry will meet at the Mayo Clinic, Rochester, Minnesota, on May 21.

Surgical clinics will be held at St. Mary's Hospital at 8:00 a.m., followed by presentation of papers at 10:00 a.m. Papers to be presented are as follows: "Chloropromazine and Reserpine in the Treatment of Chronically Ill Mental Patients," by Dr. M. C. Petersen and Dr. C. W. Baars. "Hormones and Psychoses," by Dr. Howard P. Rome. "Investigation of Environmental Factors in Schizophrenia," by Dr. Peter Beckett and Dr. Jane Watson.

Luncheon will be served at the Foundation House at 12:30 p.m. Principal speaker at the luncheon will be Dr. J. H. Tillisch, who will discuss "The History of the First Minnesota Regiment in the Civil War."

Woman's Auxiliary

INTERNATIONAL HEALTH ORGANIZATIONS—PART I

Mrs. H. F. Wahlquist

A needless cause of embarrassment to many wives of physicians is not knowing how to explain to many people just what World Medical Association and World Health Organization mean. Each of us has a vague idea of what these two organizations represent—we know they are organized for health purposes, but we lack knowledge of their basic principles, and their differences. Perhaps circumstance has really never made it imperative that we study and ferret out facts about their organizational structure and purposes.

Constantly, I am hearing some one refer to WMA when she means WHO and vice versa. As wives of physicians, we must know more about these two organizations. They are both related to medicine, and yet both are basically different. Perhaps one of the most basic differences is that WMA is made up of physicians; WHO of technical representatives of member states. As wives of physicians, we need to know more than this!

In these few brief paragraphs, I shall attempt to clarify the purpose of each organization and in later comments describe the organizational structure and functions of each.

The World Medical Association (WMA) and World Health Organization (WHO) are two international organizations. The WMA is non-governmental; it is an organization of national medical associations and its members are solely physicians. I say "solely," for in the United States a WMA U. S. Committee, Inc., of which other citizens may become a member, has been formed. The WHO is inter-governmental; it is a branch of the United Nations and represents the governments of the world in the field of health. It is a specialized technical agency of the United Nations system, but under a separate treaty with membership independent of membership in the United Nations and with its own governing assembly. The WHO is supported entirely by government funds. The WMA is supported by dues and voluntary contributions.

When the Constitution of WHO was written in 1946, specific functions were assigned in three general categories:

1. Functions relating to international sanitary regulations, causes of death, nomenclature of diseases, new drugs.

2. Coordination of health activities of governments for the eradication of epidemic and endemic diseases, the promotion of research in fields of public health and the promotion of improved standards in the medical and related professions.

3. Assistance to governments in strengthening national health services, furnishing technical assistance, promotion of improved housing, nutrition and sanitation and the promotion of maternal and child health.

Its real objective is to aid in the long term solution of a country's health problems through strengthening the national health service, rather than developing *specific programs.*

The World Medical Association aims to promote closer ties among the national medical organizations and thus among the physicians of the world. It seeks to serve as a forum for discussion of mutual problems. Its aim is to disseminate information and to raise the standards of health, medical education and medical care throughout the world. Through its officers, it can present the points of view of the medical profession before other international bodies; as WHO, UNESCO, giving physicians a voice in international affairs when matters of medicine and health are discussed. Perhaps the most significant of its aims is to work toward world peace.

(Parts II and III will appear in succeeding issues.)

CLARKFIELD HOLDS HEALTH DAY

Sponsored by the Clarkfield Community Hospital Auxiliary, a successful "Health Day" was held on Saturday, April 2, in the High School Auditorium in Clarkfield.

Mrs. M. I. Hauge, first chairman of the hospital auxiliary and state chairman of *Today's Health* for the Woman's Auxiliary to the Minnesota State Medical Association, served as chairman of a very active health day committee.

The afternoon and evening programs included a talk on "Child Accidents" by Dr. A. B. Rosenfield, Minnesota Department of Health, a talk on mental health by Rev. Fred Norstad, President, Citizens' State Mental Health Association, and panel discussions on child health, the aging population and the new wonder drugs. Music and numerous information booths helped round out an excellent program to a large crowd from Clarkfield and the vicinity.

RAMSEY AUXILIARY REPORTS ACTIVITIES

Mrs. L. T. Simons

Mrs. W. P. Gardner, president, called a board meeting on April 18 in the Medical Arts Library. Members made cancer dressings during and following the meeting. Annual reports of all committee chairmen were presented and plans for the May meeting were discussed.

Mrs. Duane Ausman and Mrs. E. R. Sterner, hospitality chairman and co-chairman, took reservations for the monthly luncheon meeting, held in the Commodore Hotel on April 25. Mrs. S. M. Loken, program chairman, presented Dr. Clarence Rowe, assistant teaching professor in psychiatry at the University of Minnesota and director of the Hamm Memorial Psychiatric Clinic, who was the main speaker on the program.

In Memoriam

RUDOLPH A. BEISE

Dr. Rudolph A. Beise, Brainerd physician, died April 4, 1955. He was seventy-eight years old.

Dr. Beise was born in Medo, Minnesota, in 1877. He attended school in Mankato before going to the University of Minnesota and Rush Medical School. He interned at Cook County Hospital in Chicago and started his practice in Brainerd soon afterward.

During his active life, Dr. Beise participated in many civic affairs. He was mayor of Brainerd from 1915 to 1919. He was a member and secretary of the Brainerd Park Board. In 1953, Governor C. Elmer Anderson selected him to represent Minnesota at the First Western Hemisphere Conference of the World Medical Association.

Dr. Beise was a vestryman of St. Paul's Episcopal Church. He was a charter member of the Brainerd Rotary Club and served as its president from 1923 to 1924. In 1951, the club held a testimonial dinner honoring him for his fifty years as a practicing physician.

Dr. Beise was chief of staff at St. Joseph's Hospital in Brainerd. He was a member of the Upper Mississippi Medical Society, the Minnesota State Medical Association and the American Medical Association. He was a Life Member of the State Association and a member of the "Fifty Club" for doctors who have been in practice for fifty years.

He is survived by his wife, the former Minnie Keller; a daughter, Mrs. Ruth Louise Quanstrom, Brainerd; and a sister, Ida Beise, of Ada.

HUBERT TOWNSEND SHERMAN

Dr. Hubert T. Sherman, long in practice in southern Minnesota, died March 23, 1955, in Cambridge. He had been a medical staff member at the Cambridge state school and hospital since 1944.

Dr. Sherman was born at Wykoff, Minnesota, in 1879. He attended high school at Minneapolis Central and continued his education at Hamline University and the Minneapolis College of Physicians and Surgeons, graduating in 1904.

Dr. Sherman practiced in several Minnesota locations, spending brief periods of time at Becker, Minneapolis, Grand Meadow, Bellingham and Echo. He spent many years in practice at Big Lake, Franklin, and Plainview.

While at Plainview, Dr. Sherman served as President of the Wabasha County Medical Society. He was a Life Member of the Minnesota State Medical Association and was a member of county societies where he was practicing.

He is survived by his wife, Rachel; three daughters, Mrs. Will McCoy, Rock Falls, Ill., Mrs. Clifford Kast, Aitkin, Minn., and Mrs. Roy Peterson, Mahtomedi; three sons, John and Hubert, both of Minneapolis, and Roy, of Albuquerque, New Mexico; a sister, Mrs. H. E. Hart, Long Prairie, Minn.; eleven grandchildren, and three great-grandchildren.

JAMES CORY FERGUSON

Dr. James C. Ferguson died April 17, 1955, at the age of seventy-nine. He had practiced medicine for over fifty years.

Dr. Ferguson was born at Fort Totten in what was then the Dakota territory. He attended school in Cooperstown, New York, the home town of his mother. He came west to attend the University of Minnesota, graduating in 1901.

He combined his internship with work as a pathologist for St. Joseph's Hospital in Saint Paul for several years and became a member of its staff.

Dr. Ferguson served with the army during World War I, both in this country and overseas. He was a Life Member of the Ramsey County Medical Society, the Minnesota State Medical association, and a member of the American Medical Association. He was a charter member of the Minnesota Pathological Society and a member of the Association of Military Surgeons. In 1951, Dr. Ferguson became a member of the "Fifty Club" of the Minnesota State Medical Association.

He was active in Masonic affairs and was a life member of the Minnesota Historical Society.

He is survived by his wife, Emily K.; three sons, James Cory of Lake Minnetonka and Robert Bruce and William Frederick of Saint Paul, and six grandchildren.

A sample survey of some 12,000 industrial firms, including manufacturers of chemicals and professional and scientific equipment, has been started by the National Science Foundation. Director Alan T. Waterman said the findings should be valuable to companies in planning and appraising their own research programs, "besides contributing greatly to the formulation of national policies for research." He estimated industry's contribution to the total $3.5 billion national research and development effort at around $1 billion a year. The federal government, in addition, spends about $1 billion annually to support research and development in industrial laboratories. Survey plans were worked out in consultation with National Association of Manufacturers, Industrial Research Institute and other industry groups.

Of General Interest

Dr. Karl Lundeberg, Minneapolis health commissioner, has announced that Minneapolis ranks lowest in cities of 400,000 or more for reported cases of venereal disease in 1954. Minneapolis had a rate of 18 cases of syphilis per 100,000 population. The highest rate in the nation, reported in Washington, D. C., was 517 cases per 100,000. Similarly, Minneapolis had only 84 cases of gonorrhea per 100,000 population, compared to 1,400 per 100,000 in Washington.

* * *

Among the speakers at a meeting of the fifth district of the Minnesota Society of X-Ray Technicians at Mankato on March 13 was **Dr. J. W. Burnett** of New Ulm. Dr. Burnett spoke on "Urinary Tract Examination."

* * *

Dr. Henry W. Meyerding, Rochester, who retired in November, 1949, as professor of orthopedic surgery in the Mayo Foundation, has been elected an honorary member of the Turkish Surgical Association and an honorary fellow of the Philippine College of Surgeons.

Dr. Meyerding recently completed an around-the-world tour by airplane. Countries he visited included Hawaii, the Philippines, Japan, China, India, Thailand, Pakistan, Lebanon, Turkey, Israel, Greece, Italy, Iceland and France. Chapters of the International College of Surgeons were installed and lectures were given at various universities and surgical meetings.

* * *

Dr. Henry E. Michelson, Minneapolis, has been invited to address the 1955 annual session of the Michigan State Medical Society in Grand Rapids, Michigan, on the subject, "Dermatological Diagnosis and Treatment."

* * *

Dr. Wendell L. Downing, Le Mars, Iowa, a graduate of the University of Minnesota Medical School in 1919, has been named president-elect of the Iowa State Medical Society. Dr. Downing has been a member of the organization's board of trustees and was chairman of it last year. In February he was elected president of the Sioux Valley Medical Society.

* * *

Principal speaker at a clinical conference at the Community Memorial Hospital, New Prague, on March 15 was **Dr. Stuart W. Arhelger,** assistant professor in the department of surgery at the Mayo Memorial Hospital, University of Minnesota. He discussed the diagnosis and treatment of cancer. The clinical conference was one of a series sponsored by the Minnesota Department of Health, Minnesota State Medical Association, University of Minnesota, Minnesota Heart Association and Minnesota Cancer Society.

Guest consultant at a clinical conference at the Kanabec Hospital, Mora, late in March was **Dr. Paul Winchell,** staff member of the Variety Club Heart Hospital at the University of Minnesota. He discussed diseases of the heart.

* * *

Dr. H. H. Russ, Blue Earth, was guest speaker at a meeting of the Kiester Parent-Teacher Association at Kiester late in March. He spoke on cerebral palsy and showed a motion picture on the same subject.

* * *

Dr. Tray G. Rollins, formerly of Elmore and now located at Cass Lake, has been awarded a fellowship in dermatology at the Mayo Clinic, Rochester, effective January 1, 1956.

* * *

Dr. E. L. Penk, Springfield, has been appointed to a three-year term as Springfield's health officer. He replaces **Dr. W. G. Nuessle,** whose term of office has expired. Dr. Penk also heads the Springfield board of health.

* * *

Fathers and expectant fathers heard **Dr. Milton L. Kaiser,** New Ulm, discuss the anatomy and physiology of reproduction and the responsibilities of fathers at a parent education meeting in New Ulm late in March. Two motion pictures on the subject were also shown. The session was the last in a series of parenthood classes sponsored by the Union Hospital at New Ulm.

* * *

Dr. Dale Cameron, medical director of the Minnesota Department of Public Welfare, was the principal speaker at a meeting of the Minneapolis and St. Paul sections of the National Council of Jewish Women in St. Paul on April 4. Dr. Cameron spoke on mental health problems in Minnesota and the work of volunteers in mental health programs.

* * *

Dr. S. J. Raetz, Maple Lake, attended a meeting of the International Academy of Proctology in New York City during the last week of March. While at the meeting he also attended lectures and surgical clinics at the Jersey City Medical Center.

* * *

Childhood accidents were discussed by **Dr. Thomas Murn,** Thief River Falls, at a meeting of the Oklee Parent-Teacher Association in Oklee late in March.

* * *

Dr. E. H. Rynearson, Rochester, has been named by the board of managers of the Gamehaven Foundation as general chairman of the Camp Building Fund Campaign, a drive to raise funds for improvement of scout camps near Rochester and Lake City.

Dr. G. W. Clifford, Alexandria, was guest speaker at a meeting of the Woman's Club in Alexandria on April 4. Dr. Clifford spoke on the subject, "Understanding Old Folks."

* * *

Dr. and Mrs. Robert N. Bowers, Lake City, spent an eleven-day vacation trip in Haiti, Jamaica and Cuba during the middle of March. They made the journey by air. While in Cuba they were entertained by friends, Dr. and Mrs. Carlos Menendez of Havana.

* * *

An auxiliary of Doctors Memorial Hospital, Minneapolis, has been organized by **Dr. Olga S. Hansen** to assist the hospital and its patients.

* * *

The engagement of Suzanne Elizabeth Scott, St. Paul, and **Dr. Thomas H. Kirschbaum**, Minneapolis, has been announced. A graduate of the University of Minnesota Medical School, Dr. Kirschbaum interned at University Hospitals. At present he is on active duty with the Navy at San Diego.

* * *

Principal speaker at a meeting of the Kiwanis Club at Alexandria late in March was **Dr. L. F. Wasson** of Alexandria, who spoke on the topic, "Does Cigarette Smoking Cause Cancer?" He discussed the opinions of groups on both sides of the somewhat controversial question.

* * *

Fifty-four members of the Chicago Surgical Society visited Rochester on March 25 and 26 for scientific sessions, observations of operations and tours of the Medical Sciences Building. **Dr. John M. Waugh** of the Mayo Clinic was in charge of the two-day affair. During the scientific sessions papers were presented by fellows in the Mayo Foundation and by members of the clinic staff.

* * *

Dr. A. O. Swenson, Duluth, president of the Minnesota State Medical Association, has been named a member of the advisory board of the Minnesota Poll, a public opinion survey conducted by the Minneapolis *Tribune* as a public service.

* * *

Dr. and Mrs. S. W. Harrington, Rochester, returned home in mid-March after spending almost two months in South America. During their tour Dr. Harrington, a retired staff member of the Mayo Clinic, presented lectures at several colleges and universities. He received an honorary award from the University of Buenos Aires.

* * *

June 26 has been designated as Dr. McKaig Day for the residents of Pine Island and surrounding communities. On that date they will celebrate the birthday of **Dr. Carle B. McKaig** and honor him for his half-century of medical service. Committees have been formed, and the citizens of Pine Island are busily preparing for the event.

* * *

Dr. C. E. Anderson, who became resident physician at Stillwater Prison on February 15, has resigned from the post because of illness.

* * *

Dr. and Mrs. O. K. Behr and their two sons have returned to Crookston after a six months' absence, during which time Dr. Behr had a senior residency in urology at the San Diego County Hospital in California. While Dr. Behr was in California his practice at Crookston was conducted by Dr. Norman R. Haugan, who is now in practice at Park Rapids.

* * *

Among the speakers at the Upper Midwest Business and Industrial Forum on Problem Drinking, held in Minneapolis on April 12, was **Dr. Charles W. Mayo**, Rochester. Dr. Mayo spoke on "People Who Overdrink." The meeting was conducted by the Upper Midwest Foundation on Problem Drinking, assisted by the Minneapolis Chamber of Commerce and the Salvation Army.

* * *

Dr. Donald E. Dille, Litchfield, left for Fort Sam Houston, San Antonio, Texas, on April 3 to report for a two-year tour of duty in the Army. Dr. Dille has been associated with the Litchfield Clinic since 1946. While he is in service his duties as Meeker County coroner will be carried out by **Dr. Harold Wilmot**, previously deputy coroner.

* * *

Two staff members of the University of Minnesota were the principal speakers at a one-day institute for private duty nurses held at the Midway YMCA, St. Paul, by the Minnesota Nurses Association on April 21. Speaking on the cross-circulation technique for intra-cardiac surgery was **Dr. Raymond Reed**, while **Dr. P. H. Soucheray** discussed the psychosomatic aspect of illness in older persons.

* * *

A biographical sketch of **Dr. Samuel G. Balkin**, Minneapolis, appeared in the Town Toppers column in the Minneapolis *Star* on April 6. The article described Dr. Balkin's civic and professional activities. Town Toppers features brief biographies of leading citizens of Minneapolis each day.

* * *

The Minnesota department of the Veterans of Foreign Wars recently presented the University of Minnesota with a certificate announcing that the organization had raised over $100,000 in its campaign to get $450,000 for a cancer research institute to be built at the University. Accepting the certificate for the University were J. L. Morrill, president, and **Dr. Owen H. Wangensteen**, chairman of the department of surgery. The VFW group voted at its annual meeting in 1953 to raise the money needed to build an eleven-bed nine-laboratory center without public solicitations for donations. It passed the $100,000 mark in less than eighteen months.

* * *

Dr. Kenneth H. Peterson, Hutchinson, left for Fort Sam Houston, Texas, on April 3 to report for a two-year tour of duty in the Army. He holds the rank of captain in the reserve. Dr. Peterson has practiced at Hutchinson for the past ten years.

* * *

Dr. E. V. Allen, Rochester, was chairman of a symposium on hypertension at a postgraduate course conducted by the American College of Physicians in New York City late in March.

* * *

The prevention and treatment of ski injuries was the topic discussed by **Dr. Vernon D. E. Smith**, St. Paul, at a meeting of the American College of Surgeons at Sun Valley, Idaho, April 18 to 20.

* * *

Dr. R. B. J. Schoch, St. Paul health officer, was guest on "The Doctors' Round Table," a television show on WCCO-TV, on the last Sunday in March. Dr. Schoch discussed a case study made in St. Paul on the spread of tuberculosis in a family.

* * *

Dr. Donald R. McFarlane, associated with the Oliver Clinic in Graceville, reported at Fort Sam Houston, Texas, on May 8 to put in a two-year tour of duty in the Army.

* * *

Dr. Thaddeus J. Litzow, Rochester, has been appointed to the staff of the Mayo Clinic as a consultant in plastic surgery and laryngology. Dr. Litzow entered the Mayo Foundation in 1951 and was an assistant to the staff from 1953 to April, 1954.

* * *

Among Minnesota physicians attending the seventh annual scientific assembly of the American Academy of General Practice at Los Angeles, California, during the last week of March were the following: **Dr. J. A. Cosgriff, Sr.**, Olivia; **Dr. H. L. Huffington**, Waterville; **Dr. O. B. Fesenmaier**, New Ulm; **Dr. C. A. Wilmot**, Litchfield; **Dr. William E. Johnson**, Morgan; **Dr. H. E. Drill**, Hopkins; **Dr. B. F. Pearson**, Shakopee; **Dr. E. J. Tanquist**, Alexandria, and **Dr. E. W. Lippmann**, Hutchinson.

* * *

Winner of second place by popular ballot at the 1955 Rural Art Show in the Agricultural Library at the University campus, St. Paul, was a painting by **Dr. Paul F. Brabec**, Hastings. Dr. Brabec's painting, entitled "Captain Bill," was entered in competition among painters from towns of under 10,000 population. Over 400 entries were received for the show, which was attended by 2,000 visitors.

* * *

Dr. T. M. Seery, Austin, attended a series of lectures on "Pathology and Pathologic Physiology in Internal Medicine" at the Frank E. Bunts Educational Institute in Cleveland late in March. The lectures were presented by the Cleveland Clinic Foundation.

* * *

Dr. and Mrs. Frank E. Mork, Anoka, returned in mid-March from a trip through the South. During the journey Dr. Mork attended the annual meeting of the Graduate Medical Assembly in New Orleans, Louisiana.

* * *

Several section changes at the Mayo Clinic, Rochester, became effective April 1. **Dr. R. K. Ghormley** became senior consultant in orthopedic surgery, with **Dr. H. H. Young** as chairman of section. **Dr. F. A. Figi** became senior consultant in the section of plastic surgery, with **Dr. J. B. Erich** as head of section. **Dr. W. McK. Craig** became senior consultant in the section of neurosurgery, with **Dr. J. Grafton Love** as head of section.

* * *

Dr. R. H. Puumala attended a three-day course in radiology at the University of Minnesota Continuation Center on April 11, 12 and 13.

* * *

Dr. Douglas L. Johnson, Little Falls, began a fellowship in ophthalmology at the University of Minnesota on March 28. On completion of the graduate study he plans to return to Little Falls and limit his practice to ophthalmology.

* * *

Principal speaker at a meeting of the Lions Club in Mabel late in March was **Dr. Joseph F. Schaefer**, Owatonna. The meeting was held in honor of the local Boy Scouts.

* * *

Three Minnesota surgeons participated in a sectional meeting of the American College of Surgeons at Winnipeg, Canada, April 25 and 26. They were **Dr. Morley Cohen** and **Dr. W. Robert Schmidt**, Minneapolis, and **Dr. John C. Ivins**, Rochester.

* * *

Guest consultant at a clinical conference at the Municipal Hospital at Wells on March 28 was **Dr. Alan P. Rusterholz** of the department of medicine at the University of Minnesota. He discussed heart disease at the conference, which was sponsored by several Minnesota medical organizations.

* * *

Dr. and Mrs. S. T. Kucera, Northfield, returned in late March after a three-week tour of the southern states. While on the trip Dr. Kucera attended the eighteenth annual meeting of the New Orleans Graduate Assembly.

* * *

Dr. Thomas L. Pool, Rochester, associate professor of urology in the Mayo Foundation, was a consultant in medicine at a Career Conference at Knox College, Galesburg, Illinois, recently. Experts from twenty-six vocational fields attended the conference for a day of counseling and meeting with students.

* * *

A biographical sketch of **Dr. Ivar Sivertsen,** Minneapolis, in the Town Toppers column of the Minneapolis *Star* on April 14 emphasized the physician's early affiliation with Fairview Hospital. Dr. Sivertsen admitted the first patient to the hospital in 1916 and performed the first operation in the hospital's old operating suite.

* * *

Dr. Jack A. Guy, New London, now with the U. S. Public Health Service, expects to return to his practice at New London about June 1. He recently completed a two-week course in fractures and traumatic surgery at the Cook County Postgraduate School of Medicine in Chicago.

* * *

Dr. and Mrs. C. J. Olson, Belle Plaine, returned on April 7 from a vacation trip to California and Texas. While in San Diego, Dr. Olson attended an institute in heart disease at the naval hospital.

NEW LOCATIONS

Dr. R. G. Ziegler has announced that he will discontinue his practice at Welcome about May 22 and will move to Brush, Colorado. Beginning July 1, he will be affiliated there with the Brush Clinic. He has practiced at Welcome since 1951.

* * *

Dr. John W. Schut opened offices for the practice of medicine in Anoka on April 1. A graduate of Northwestern University Medical School, he was a resident at the University of Minnesota for two years and served as a psychiatrist at the Anoka State Hospital for another two years. Until recently he was doing research at the Galesburg State Research Hospital, Galesburg, Illinois.

* * *

Dr. Wallace E. Anderson has announced that he will leave Lakeville in July to become associated in practice with **Dr. Stanley Stone,** Minneapolis. Dr. Anderson has practiced at Lakeville since July, 1952.

* * *

Dr. Norman Haugan, formerly of Crookston, opened offices for the practice of medicine in Park Rapids on April 1. After graduating from the University of Minnesota Medical School in 1953, Dr. Haugan practiced in Watertown before moving to Crookston where he was associated with the Crookston Clinic.

MINNESOTA BLUE SHIELD-BLUE CROSS PLANS

Blue Shield

At a Blue Shield professional relations meeting held in Chicago on February 24 and 25, 1955, over 100 representatives of Blue Shield Plans throughout the country were present to review and evaluate methods used in professional relations programs. Arthur J. Doherty, of Minnesota Blue Shield, found that the whole program was devoted to consideration of means of providing greater service to the doctor, bringing information about Blue Shield directly to the doctor, and creating a closer relationship between the doctors and the Blue Shield Plans.

At the conclusion of these sessions, it was the opinion of those present that developing closer liaison between the doctor and Blue Shield through personal visits is the most effective feature of any such program. This method of improving professional relations is being used by many of the Blue Shield Plans in other states and has proved successful in securing the necessary close relationship and understanding between the doctor and Blue Shield.

Minnesota's Blue Shield program of professional relations is strikingly similar to that carried on in other states. In October, 1954, the Minnesota program became fully active. Since then, three Blue Shield field representatives have made over 1800 personal calls to doctors' offices. In more than 25 per cent of these calls, the doctor has been personally visited. When the doctor has not been available, various features of Blue Shield have been discussed with the members of his office staff. In each instance, the Blue Shield contract and procedures are explained to the doctor and his staff for clarification of Blue Shield objectives of subscriber benefits, claims reporting, and payment of claims.

During the first two months of 1955, maternity cases ranked first in frequency of occurrence for hospitalization of Blue Cross subscribers, respiratory illnesses ranked second and accidents third.

Blue Cross

The number of maternity cases paid during the first two months of this year totaled 4,302, a slight increase over the 4,277 cases paid during the same period of 1954. Maternity benefits of $463,106.08 were provided by Blue Cross during the first two months of 1955.

Although respiratory illnesses ranked second in frequency of occurrence during the first two months there was a slight decrease in the number of cases over the previous year. There were 3,857 respiratory cases for the first two months of 1955 with Blue Cross respiratory benefits totaling $309,102.19.

Accident cases numbered 3,599 for the first two months of 1955 and the Blue Cross accident benefits allowance amounted to $190,888.17.

Since 1933, $113,979,811.15 has been provided by Minnesota Blue Cross for hospital care of subscribers.

During the month of February, 1955, 4,056 contracts representing 10,171 participant subscribers were enrolled in Blue Cross bringing the net enrollment as of February 28, 1955 to 1,003,104 participant members.

BOOK REVIEWS

Books listed here become the property of the Ramsey, Hennepin and St. Louis County Medical Libraries when reviewed. Members, however, are urged to write reviews of any or every recent book which may be of interest to physicians.

BOOKS RECEIVED FOR REVIEW

CLINICAL DISORDERS OF HYDRATION AND ACID-BASE EQUILIBRIUM. Louis G. Welt, M.D. Professor of Medicine, Department of Medicine, University of North Carolina. 262 pages. Illus. Price $6.00, cloth. Boston: Little, Brown & Co., 1955.

DEMONSTRATIONS OF PHYSICAL SIGNS IN CLINICAL SURGERY. 12th Edition. Hamilton Bailey, F.R.C.S. (Eng.), F.A.C.S., F.R.S.E., Emeritus Surgeon, Royal Northern Hospital, London; General Surgeon, Metropolitan Ear, Nose and Throat Hospital; Consulting Surgeon, Italian Hospital; Hunterian Professor, Royal College of Surgeons; formerly External Examiner in Surgery, University of Bristol. 456 pages. Illus. Price $8.00, cloth. Baltimore: William & Wilkins, 1954.

BRUCELLOSIS. M. Ruiz Casteñeda. Director del Departmento de Investigaciones Médicas, Hospital General, México, D. F. Miembro del Comité de Expertos en Brucelosis de la Organizatión Mundial de la Salud. 302 pages. Illus. Mexico, D. F.: La Prensa Medica Mexicana, 1954.

THE TEMPOROMANDIBULAR JOINT. Edited by Bernard G. Sarnat, M.S., M.D., D.D.S., F.A.C.S., Professor and Head of the Department of Oral and and Maxillofacial Surgery, College of Dentistry; Clinical Assistant Professor, Department of Surgery (Plastic Surgery), College of Medicine, University of Illinois, Chicago, Ill.; Diplomate of the American Board of Plastic Surgery. 148 Pages. Illus. Price $4.75. Springfield, Ill.: Charles C Thomas, 1951.

This small volume by five faculty members of the dental schools of three universities in Chicago discusses the anatomy, physiology, and pathology of the temporomandibular joint with emphasis on the dental aspects. The Costen syndrome, attributing numerous auditory and vestibular symptoms to dysfunction of the temporomandibular joints, is thoroughly evaluated with the conclusion that it is not supported by facts and should be abandoned. The book is strictly limited in its objectives and makes no pretense at covering all the clinical features of the temporomandibular joints.

Elmer C. Paulson, M.D.

BONE TUMORS. By Louis Lichtenstein, M.D., Senior Pathologist, General Medical and Surgical Hospital, Veterans Administration Center, Los Angeles. 315 pages. Illus. Price $10.50. St. Louis: The C. V. Mosby Company, 1952.

The introductory chapter stresses the importance of biopsy in conjunction with roentgenographic examination of suspected bone tumors before treatment is attempted. Since many new skeletal lesions, both neoplastic and non-neoplastic, have recently been described, the necessity for open-mindedness is emphasized.

A classification of bone tumors is presented for consideration as a helpful working hypothesis, along with pertinent comment in support of proposed categories.

The chapters on bone tumors describe the clinical features, pathology, radiograms and therapy of various bone tumors. An appendix discusses some lesions of bone often mistaken for tumors.

The text is adequate and readable. The illustrations include radiograms, gross photographs, and photomicrographs of good quality. There is an adequate bibliography with each chapter. This book will prove itself useful to pathologists, surgeons, and radiologists alike.

J. W. James, M.D.

PRIMER OF ALLERGY; A GUIDEBOOK FOR THOSE WHO MUST FIND THEIR WAY THROUGH THE MAZES OF THIS STRANGE AND TANTALIZING STATE. By Warren T. Vaughan, M.S., M.D., Richmond, Va. Illustrations by John P. Tillery, 4th edition, revised by J. Harvey Black, M.D., Dallas, Texas. 191 pages. Price $4.25. St. Louis: C. V. Mosby Co., 1954.

This book has fulfilled its primary purpose. It is an interesting book on allergy which will be read by the intelligent patient and enable him to co-operate with his doctor. It is written in a style which stimulates the patient to do his best in treating his allergies. Every practicing physician will do the patient and himself a favor by introducing the patient with an allergic disease to this short book. The language of the doctor will no longer be just a lot of words after the patient has read this book.

The secondary purpose of this book, that of giving concise information to the physician doing a minimum of allergy work, has also been fulfilled. However, this reading should be expanded by reading a larger book in the field of allergy as soon as the physician's time permits.

Donald W. Koza, M.D.

MOTION PICTURE FILMS

A completely revised Fourth Edition of "Professional Films" is now in compilation. (The frequency and number of future insert pages necessary to assure a comprehensive index that is continuously current over a period of years will be determined by the volume of forthcoming productions.) It will include new sections providing biographical data on authors, and information on the audio-visual activities of medical schools, dental schools and graduate teaching centers.

Over 28,000 copies of previous editions are in use by medical and dental schools, program chairmen of state and specialty societies, and others here and abroad. Academy-International of Medicine provides this valuable audio-visual information to the profession-at-large, without profit, as one of its contributions toward elevating the standards of medical and dental services by expediting the dissemination of professional knowledge.

You are urged to directly assist by (1) informing film authors of this announcement so that they can write for questionnaires, or (2) providing the film title and full name and address of any film author. Write to the Academy-International of Medicine, 601 Louisiana Street, Lawrence, Kansas.

Tetanus

A Summary of Thirty-two Cases with Special Reference to Prevention

VICTOR A. GILBERTSEN, M.D., and
STUART W. ARHELGER, M.D.
Minneapolis, Minnesota

TETANUS, known as a clinical entity since the time of Hippocrates, continues to occur and to command a high fatality rate. Although effective active immunization is well established, the wide dissemination of the hardy spore form of the causative organism in association with its regular presence in the gastrointestinal tracts of most domestic animals makes the disease a difficult one to eradicate. Because more than one case is rarely seen by any one physician, it seems worthwhile to review certain aspects of clinical tetanus with special reference to prevention of mortality.

Cases

During the past ten years (1943-1953), thirty-two cases of tetanus were seen at the University of Minnesota Hospitals (Table I). The ages of the patients ranged from twenty months to eighty-one years. One half of the patients were sixteen years of age or younger; the mortality was 25 per cent in this group. Nine patients were over fifty years old; of these, six (67 per cent) died.

The time intervals from injury to the first symptom, in those cases where the data are available, are listed in Table II. An initial injury was apparent in thirty of the thirty-two cases. The variety of injuries, the causative mechanism, and the sites of injury are summarized in Table III.

The initial symptoms of tetanus, the events that informed the patient that he was sick, are summarized in Table II under the headings of trismus, spasm of dorsal muscles, extremity muscle spasm, and influenza-like onset. Onset with trismus was most common; nineteen (60 per cent) of the patients in the present series are included in this group, and seven of the nineteen later succumbed to the disease. These patients usually experienced difficulty in eating, but this may have been referred to by the patient as "stiffness" of the tongue or dysphagia.

TABLE I. AGES OF PATIENTS

Age	Patients	Deaths	Mortality
Under 6 years	9	2	22%
7-16 years	7	2	29%
17-50 years	7	0	—
Over 50 years	9	6	67%
Totals	32	10	31%

TABLE II. INCUBATION PERIODS

Total Group (29 Cases)	Fatal Cases (9 Cases)
Range: 3-23 days	Range: 4-13 days
Average: 9 days	Average: 8.7 days

Patients with spasm of the dorsal muscles usually noted spasm, pain, or tenderness of the back or cervical muscles which occasionally progressed to opisthotonus. Six patients are herein included; two died. The patients who presented spasm of the extremity muscles noted spasm or "stiffness" of the extremities. Four patients are in this group; one died. Patients with influenza-like onset noted generalized body aching and malaise; sometimes generalized but minimal stiffness or pain in many muscle groups was present. There were three patients with this type of onset; no deaths occurred.

It is of particular interest that several of the injuries that were followed by tetanus were grossly clean wounds or were cleansed in a manner which would seem likely to have removed contamination (Table V). It seems possible that these wounds were free of tetanus organisms at the time of the original injury but were contaminated at some later date, before healing had

---

TABLE III. INJURIES FOLLOWED BY TETANUS

Cases	Instrument or Mechanism	Injured Portion of Body	Fatalities
7	Sharp instrument	Hand or finger	1
4	Nail	Foot	3
3	Sharp instrument	Foot	—
2	Wood sliver	Hand	—
2	Burn	Extremities	2
2	Unknown	—	—
1	Nail	Hand	—
1	Nail	Forehead	—
1	Barbed wire	Foot	1
1	Wood sliver	Toe	—
1	Tree branch	Leg	1
1	Bush	Leg	—
1	Broken glass	Buttocks	—
1	Dynamite	Elbow and forehead	—
1	Roadway	Scalp	1
1	Twig	Gingiva	—
1	Compound fracture	Finger	—
1	Autoexcoriation	Leg ulcer	1

taken place. The contamination of an originally clean wound, which may have occurred in these cases, rarely has been stressed as a significant feature in the etiology of tetanus.

Ten patients in this series died. Autopsies were carried out in eight. The significant autopsy findings, and the probable causes of death in those cases where benefit of autopsy was not obtained, are listed in Table VI.

Discussion

While this series of thirty-two cases of tetanus is relatively small and therefore not subject to strict statistical analysis, several features are of clinical interest. The observation has been made elsewhere that tetanus is no longer the scourge of the parturient mother, the newborn babe, and the wounded soldier.[1] The recent cases seen at the University Hospitals occurred chiefly among rural residents. The fatalities were largely in persons whose age or physical condition seems to have made them less able to withstand the respiratory complications which invariably accompany the full-blown case.

Prompt recognition of the disease, once the initial symptoms have appeared, should lead to earlier treatment and likely to better chance of cure. Early diagnosis of tetanus remains clinical in spite of some aid from the laboratory. The earliest symptom in the cases presented here was almost always related to some type of muscle spasm. The majority of the patients had spastic involvement of the jaw muscles as an initial symptom; some expressed this as pain, difficulty with eating, or dysphagia. Several patients first noted spasm of other muscles—especially those of the back and neck. A few had spasm or stiffness of the arms or legs. It is likely that trismus which cannot otherwise be readily explained—especially when associated with spasm of the back muscles—should be presumed due to tetanus.

TABLE IV. FIRST SYMPTOMS OF TETANUS

Group	Cases	Symptom
Trismus	13	Trismus
	3	Dysphagia
	2	"Stiff" or "swollen" tongue
	1	Pain in the jaw
Spasm of the dorsal muscles	2	Stiff neck
	2	Backache
	1	Spasm of back muscles
	1	Opisthotonus
Extremity muscle spasm	2	"Wooden gait"
	2	Spasm or "twitching" of the extremities
"Flu"-like onset	2	Generalized muscle aching
	1	Abdominal pain and body "stiffness"

When considering the natural history of tetanus, it has been generally assumed that those who fall victim to the disease have had the spores introduced into a wound at the time of initial injury. The suggestion has been made only infrequently that some of those who develop clinical tetanus may have had wounds that were at first free of the organism, but by one route or another the spores entered the wound later—before healing was complete.[2] Consideration of the mode of infection in wounded soldiers in World War I has led to the impression that many of the bullet wounds were originally "clean" but that contaminated soil from the fields may have gotten into the wounds before the patients reached medical aid.[3] Striking, however, is the observation by Stitts[4] that natives lacerated by the barb-like tail of the sting ray have developed tetanus—presumably after clean wounds were contaminated later with soil containing tetanus spores.

Although the exact modes of tetanus infection in the five patients presented in Table V remain problematical, they serve to emphasize that open wounds, especially if infection or tissue necrosis is present, may offer ideal ground for the growth of the tetanus organism. Debridement of wounds and eradication of other infecting bacteria continue to be measures considered necessary to destroy conditions which are favorable for the growth of the tetanus organism and the development of the disease.[5] The additional precaution of safeguarding unhealed wounds from secondary contamination with Clostridium tetani is likely important.

TABLE V. PATIENTS WITH POSSIBLE LATER-CONTAMINATION

Case Number	Age in Years	Sex	Probable Portal of Entry of Organism	Treatment of Injured Locale	Conditions Favoring Late Contamination	Injury to Symptoms
1	76	M	Postphlebitic leg ulcer	None	Worked in garden; often excoriated leg and ulcer	10 years
2	4	M	Heel, cut on bicycle spoke	Bled profusely; treated and bandaged by a physician	Up and about house and yard; wound "dirty" on admission	17 days
3	9	M	Toe, cut with a wood saw	Cleansed and sutured by a physician	Dressings often soiled as child was about the farm	15 days
4	56	M	Hand, cut with a buzz saw	Treated by a physician; 1500 units of tetanus antitoxin given	Continued most of farm duties; wound unhealed on admission	13 days
5	61	M	Fingers, cut with a circular saw	Treated by a physician; 1500 units of tetanus antitoxin given	Worked on farm after the injury; infected fingers noted on admission	21 days

TABLE VI. FATAL CASES

Age in Years	Sex	Tracheotomy	Autopsy	Cause of Death
9	M	None	Yes	Pneumonia and "respiratory failure"
7	M	Delayed	No	Pneumonia and partial tracheal obstruction
4	M	Delayed	Yes	Pneumonia
63	F	None	Yes	Aspiration pneumonia, atelectasis, and pulmonary congestion
4	F	Delayed	Yes	Pneumonia, atelectasis, and cerebral edema
77	M	Delayed	Yes	Pneumonia, atelectasis, and pulmonary congestion
65	M	Prompt*	Yes	Ruptured midcolic artery, aspiration pneumonia, and atelectasis
76	M	Prompt	Yes	Pneumonia and atelectasis
57	M	Prompt	No	Pneumonia
81	F	Delayed	Yes	Pneumonia and atelectasis

*Prompt—within four hours of hospital admission.

The introduction of tetanus antitoxin represented an advance in the prevention of clinical tetanus. Prophylactic administration of this serum to wounded soldiers in the first World War probably reduced the incidence of the disease. However, the observation that several patients in this series developed tetanus in spite of the prophylactic administration of tetanus antitoxin confirms the impression of several observers that antitoxin, at least in the common prophylactic doses of 1500 units, cannot be regularly relied upon to prevent the development of clinical tetanus.[6,7] The presence of occasional hypersensitivity to the horse serum of the antitoxin and the frequent observation that many of the patients who develop tetanus in civilian life do not seek medical attention at the time of injury, somewhat detract from the usefulness of the antitoxin in prophylaxis and further emphasize the desirability of active immunization with the toxoid.

It has been stated that active immunization with tetanus toxoid affords protection from the disease.[8] This impression is confirmed by reports in regard to World War II which indicate that of five million Navy personnel immunized with the toxoid, only four contracted the disease during the war, and of the four only two (both without record of complete immunization) died.[9] During a comparable period of time, about 2,500 deaths from tetanus were reported in the civilian population of this country.[10] In the present series of thirty-two cases, none of the patients had received the toxoid. Active immunization with tetanus toxoid should be readily available and routinely administered to those persons who are likely to sustain frequent small injuries, to those exposed to animal excreta, and to all children.[11,12]

A detailed discussion of therapy is not the purpose of this paper, but it may be noted that the problem of prevention of death from the disease is largely one of prevention of serious respiratory complications. The fatalities in the present group, like those in most series recently reported, serve to illustrate the gravity of pulmonary complications; of the ten patients in this group who expired, nine died of atelectasis, pneumonia, asphyxia, or a combination of these. The toxin causes variable degrees of central nervous system paralysis, but some of the damage may be temporary with the aid of tetanus antitoxin.[13] If the patient can be protected from severe respiratory complications his life usually can be saved. Of chief importance in treatment of the established case of tetanus is the maintenance of an adequate upper respiratory airway, but following close behind is the necessity of adequate cleansing of secretions of the tracheobronchial tree. Tracheotomy—with constant nursing care—is admirably suited for both purposes.[14,15,16] Tracheotomy is now considered to be a prerequisite for proper treatment of systemic tetanus when any respiratory difficulties are present. A number of recent papers emphasize the treatment of respiratory complications and review current concepts of therapy of severe cases of tetanus.[17,18,19]

Conclusions

Although the salient features of clinical tetanus have changed little in the 2,000 years since their first description by Hippocrates, prophylaxis and therapy have undergone a remarkable metamorphosis. Many of the features of the present series of thirty-two cases of tetanus seen during the past ten years are consistent with traditional concepts of the disease, but certain new aspects have become worthy of emphasis. The place of the battle casualty and the newborn child as victims of tetanus has been taken by the man in the barnyard and the child on the farm. Trismus remains the most frequent presenting symtom, but variation in its mode of expression occurs in some patients; a few patients apparently are more impressed with spasm of other muscles than those of the jaw.

Several cases illustrate the notable—but not entirely new—observation that a wound may be treated originally in a seemingly adequate manner but that contamination later of the unhealed wound by tetanus spores possibly occurs. It is emphasized that in addition to debridement and cleansing of wounds, protection from contamination before healing has taken place may be of importance. The usual prophylactic dose of 1500 units of tetanus antitoxin was inadequate to prevent development of the disease in several patients. It is suggested that this dose be increased to 5,000 or 10,000 units when there is a likelihood of the presence of tetanus spores.

The thirty-one per cent fatality rate in this series, although lower than several recently reported rates of 40 to 70 per cent,[20,21,22] is nonetheless high. Deaths in this group were preceded by respiratory complications. Current fatality rates, which remain high in spite of recent advances in therapy, serve to underscore the virtue of active immunization with tetanus toxoid. Routine toxoid immunization probably should include both children and adults.

A Practical Approach to the Treatment of Tetanus

NORMAN A. CHRISTENSEN, M.D.
Rochester, Minnesota

TETANUS toxoid, used properly, has proved to be one of the most effective prophylactic agents yet developed in medicine. Part of the foundation for this declaration is my own experience acquired during the Okinawan campaign. At that time I was on the medical staff of a United States Military Government Hospital wherein between 100 to 150 nonimmunized civilians were treated for tetanus. The office of the Surgeon General of the United States Army[6] informed me that not a single case of tetanus was reported among the many thousands of members of the Armed Forces of the United States who participated in the Okinawan phase of the war. Wounds were frequent among them, and the conditions under which both they and the civilians lived were similar. Members of the Armed Forces, however, had received prophylactic injections of tetanus toxoid.

Reactions to toxoid have been reported to number only 2 per 100,000.[7] This, together with the high degree of protection and the threat of another world war, should be enough to stimulate physicians of this country to work for immunization of the entire population to tetanus. This would make unnecessary the many injections of tetanus antitoxin in horse serum which the physician is now legally obligated to administer to a wounded nonimmune person. In many cases reactions supervene, some of them serious and a few even fatal.

Alum-precipitated toxoid seems to provoke a superior antigenic response and it is recommended for basic active immunization. Fluid toxoid causes a more prompt increase in specific agglutinin (recall titer response). Thus, it is preferred as a stimulating, or so-called booster, injection, particularly when a wound arouses suspicion.[9]

Results of Treatment

The success attained in the actual treatment of tetanus falls far short of the results attained in its prophylactic treatment. Results of treatment of ten different series of patients in various parts of the world were reported in the period 1945 to 1953. Of the 960 patients concerned, 444 died of the disease or its complications; this is a mortality rate of 46.3 per cent (Table I). At the Mayo Clinic, sixty-six patients were treated for tetanus in the years 1911 to 1945 inclusive. Of these, 51.5 per cent died. From 1946 to 1954 inclusive, twenty-six patients have been treated, with a mortality rate of 26.9 per cent (table).

This reduction of the mortality rate from 51.5 per cent to 26.9 per cent may be fortuitous, but I doubt that it is. In 1946, some of us at the Mayo Clinic began to work as a tetanus team. However, it was not until about 1951 that the team began to function smoothly. Only one patient of the eight treated since 1951 has died. The team consists of internists, neurologists, orthopedists, anesthesiologists, pediatricians, plastic surgeons, clinical pathologists and bacteriologists. It is the responsibility of members of the team to be available for early diagnosis and to keep well informed concerning the most modern methods of treatment.

Fundamentals in Treatment

Tetanus is a complication of clostridial infection of a wound. The wound can be major or minor. In time of peace wounds may be trivial and often they have healed by the time the patient seeks medical attention. The infection usually is easily treated. Clinical tetanus, the result of the potent tetanus exotoxin combined with nervous tissue, on the other hand, is a formidable con-

dition. The union has taken place once the patient has symptoms. The diagnosis, by necessity, is made on clinical grounds, for time is important; moreover, cultures are slow and are helpful in only 25 to 50 per cent of cases.

*Children; †German prisoners; ‡civilians.

As yet no treatment will reverse the disease process or speed oxidation of the combined toxin. If, however, less than a lethal dose of toxin has combined with nervous tissue, the patient who has adequate treatment stands a good chance to recover. The disease is less likely to be fatal if the incubation period is longer than twelve to fourteen days. The morbidity, whether the tetanus is mild or severe, averages three to five weeks. Beginning with the tenth day after the appearance of symptoms, prognosis improves rapidly each day and, if the patient is alive beyond the fourteenth day after symptoms have appeared, he stands an excellent chance to recover without any residual. Death, when it occurs, usually results from: (1) circulatory failure; (2) asphyxia due to spasm of the glottis, diaphragm and intercostal muscles, or (3) sheer exhaustion.[2] Complicating pneumonia, cerebral edema, oversedation, or excess use of muscle-relaxing drugs along with serum reactions, have taken their toll.

Present Plan of Treatment at Mayo Clinic

The following plan of treatment is based partly on my experience in treatment of approximately seventy-five patients, some of them in the military hospital mentioned and some in the Mayo Clinic, partly on the experience of others at the clinic, and partly on experience recorded in published reports.

1. Preferably the patient is hospitalized, thus insuring close supervision and good nursing care.

2. On admission to hospital the patient is given tetanus antitoxin. The aim is to give the quantity necessary to neutralize any circulating or uncombined toxin and any that will be produced prior to elimination of the focus of infection. As yet, no method has been developed for determining the adequate amount for an individual patient. After a test for hypersensitivity has been made, 15,000 to 30,000 units are arbitrarily administered intravenously, or 10,000 to 30,000 units are given intramuscularly, either or both. The larger amounts are used when the wounds are deep, penetrating, or badly infected. Also, if symptoms are well advanced or are progressing rapidly, and therefore, it is suggested that overwhelming infection has occurred, the larger doses are used. Smaller amounts are then given for the next few days, until the focus of infection has been removed and the disease process stabilized.

Whenever tetanus antitoxin in horse serum is given, it is essential to have close at hand ampules of epinephrine, needles and syringes, along with oxygen and fluids for intravenous injection in case of anaphylactic reactions. Diphenhydramine hydrochloride (benadryl) or tripelennamine hydrochloride (pyribenzamine), in doses of 25 to 100 mg. (depending on age) every four to six hours, helps to prevent or to suppress serum reactions. These drugs also aid in sedation. Both are given by mouth.

3. The amount and kind of sedative drug used again depend on the needs of the individual. Enough is that amount that will keep the patient

reasonably comfortable and allow periods of restful sleep. Barbiturates, chloral hydrate, bromides and paraldehyde have been used to control mild or moderately severe tetanospasms. Depending on the age of the patient and the severity of the disease, tribromoethanol (avertin), 50 to 70 mg. per kilogram of body weight, has been used in a rectal retention enema; in my opinion this is the drug and the method of choice for sedative control of severe tetanospasms. Usually restful sleep for three to six hours supervenes and, on awakening, the patient frequently is sufficiently relaxed to be able to take food and fluids without too much difficulty. One or two administrations per twenty-four hours usually suffice but occasionally three injections are necessary. These enemas have been considered lifesaving in some cases at the clinic. Except for proctitis in one case, apparent side effects or reactions have been minor and few. Morphine sulfate, curare or other such respiratory depressant drugs, in my opinion, are contraindicated. Codeine and meperidine hydrochloride (demerol hydrochloride) are useful adjuncts. In addition to relieving pain, they tend to lessen the frequency with which tribromoethanol (avertin) must be used.

4. For adults, penicillin and dihydrostreptomycin in doses of 1,000,000 units and 1 to 2 gm. respectively, are as effective as any antibiotic therapy of which I know in combating Clostridium tetani and symbiotic organisms. Proportionately smaller doses are used for children. Antibiotic treatment affects the course of the disease only in helping to eradicate a focus, or foci, of infection and thus prevent production of more exotoxin. Even large doses of antibiotics cannot be entirely relied on to do this, however, particularly if wounds are deep and badly infected. Clostridia thrive in dead or dying tissue, where the blood supply is reduced or absent. Antibiotic treatment should be continued until the focus of infection has been eliminated. It is useful, too, in prevention or treatment of the pneumonia which is prone to develop in severe cases.

5. When treatment with tetanus antitoxin and antibiotics has been started, adequate débridement and other care of the wound are in order. Lethal doses of toxin often can be produced in trivial wounds. The natural tendency is to be too conservative. When amputation or extensive débridement is necessary, general anesthesia is best effected by giving thiopental sodium (pentothal sodium) intravenously, or tribromoethanol (avertin) rectally. Ether tends to be irritating to the respiratory tract, to increase laryngospasm and to predispose to pneumonia. If use of an oxidizing agent is indicated, moist potassium dichromate dressings are better, in my opinion, than hydrogen peroxide dressings, which frequently are irritating to the skin.

6. Tracheotomy should be done whenever respiration is significantly embarrassed by laryngospasm or accumulation of tracheobronchial secretions.

7. A high-caloric diet is indicated where metabolism is greatly increased. Liquid to soft foods are tolerated better than are solids. Multiple small feedings are more suitable than three large meals. A nasal tube can be used when necessary and when it does not aggravate the condition. Supplementary fluids containing glucose, proteins, electrolytes and vitamins are given parenterally when they are needed to maintain hydration, nutrition and electrolyte balance.

8. Oxygen and a portable respirator are used when indicated.

9. Urinary retention has to be relieved in some cases.

10. Cortisone, compound F (hydrocortisone) and adrenocorticotropic hormone (ACTH) are the newest preparations which apparently are useful in this condition. The action and value of hormonal therapy in tetanus have not been exactly determined. At present, the members of the team described earlier reserve use of the hormones for two groups of patients: (1) allergic patients who react to, or who are known to be hypersensitive to, tetanus antitoxin. For example: One patient had chronic asthma and hay fever. A year before his admission with tetanus, he had been given tetanus antitoxin after an automobile accident. A severe reaction followed. Intravenous administration of adrenocorticotropic hormone (ACTH) and then oral administration of cortisone made it possible to follow the usual program of administration of tetanus antitoxin.

Sheer exhaustion often is the only apparent cause of death in cases of this disease. When exhaustion becomes apparent, our team uses cortisone purely as a supportive measure in an attempt to maintain life while the patient is passing the crisis of this self-limited disease. Depending on the age, sex and condition of the patient, in the absence of absolute contraindications, 100 to 300 mg. of cortisone is given each day in divided doses, until the crisis has passed. Thereafter doses are reduced and gradually use of the preparation is discontinued. Oral administration is preferred but the substance can be given intramuscularly if necessary.

Summary

Since 1945, the mortality rate of clinical tetanus at the Mayo Clinic has fallen from 52 per cent to 27 per cent. Apparently this is attributable, not to any new treatment pariculary, unless such be the use of cortisone and adrenocorticotropic hormone (ACTH), but to the formation of a tetanus team. The team has the responsibility of aiding in early diagnosis of the disease, and of standardizing treatment so that therapeutic measures now available will be used most effectively. The present plan of treatment which the team applies is summarized in the body of the paper. One of four patients still is lost. This means that treatment of tetanus is not yet satisfactory. Although tetanus toxoid is effective in preventing the disease, and antibiotics are effective in destroying Clostridium tetani, a method which will reverse the disease process, once the exotoxin has become fixed in the nervous tissue, is lacking.

ANEMIA IN PREGNANCY

About 80 per cent of normal patients manifest decreases in hematologic values to a variable degree during pregnancy.

A physiologic anemia does not occur in pregnancy. Minimal or moderate decreases in the hemoglobin are usually the results of an iron deficiency.

Associated with any decrease in hemoglobin there is a decrease in the serum iron and elevation of the erythrocyte protoporphyrin. These have been shown to indicate the existence of iron deficiency.

A hemoglobin of 12 grams per cent has been found to be an approximate minimal normal hemoglobin for the pregnant state. Only 20 per cent of pregnant patients not receiving supplemental iron maintained their hemoglobin above 12 grams per cent.

Approximately 80 per cent of pregnant women maintained or improved their hemoglobin values when given an iron supplement with their diet.

Every pregnant woman should receive iron during pregnancy. A minimum of ninety days has been found to constitute an adequate trial. Iron should preferably be administered late in pregnancy when the iron demands are the greatest.

Ninety per cent of pregnant women maintained or improved their hemoglobin values when given a combination of iron and cobalt (Roncovite). A significantly higher proportion of patients receiving iron and cobalt delivered with a hemoglobin above 13 grams per cent when this series was compared with the iron treated series.

No toxic manifestations associated with its use have been observed.—R. G. Holly, *Obstetrics and Gynecology,* 5:1 (April) 1955.

Tumors of the Colon and Rectum

Fundamental Considerations in Diagnosis and Treatment

WALTER A. FANSLER, M.D., and
WILLIAM T. SMITH, M.D.
Minneapolis, Minnesota

THE PURPOSE of this paper is primarily as an aid to diagnosis and treatment of benign and malignant tumors of the colon and rectum. Since the majority of these tumors will be either adenomas or carcinomas, most of it will deal with their detection and treatment. The physician should never rule out neoplasms of the colon and rectum on the basis of history alone. Many tumors present in the large bowel and rectum may be asymptomatic or present symptoms such as flecks of blood in the stool which are undetected by the patient. For this reason every complete physical examination should include a digital and also a proctoscopic examination of the terminal bowel. A carefully done digital examination should rule out neoplasms of the anal canal and distal rectum. A proctoscopic examination to 25 cm. will reveal 75 per cent of the tumors of both the rectum and the large bowel.

The commonest malignant tumor arising from the anal canal is a squamous cell carcinoma. This may arise from either the perianal skin or from the skin lining the anal canal proper. It should be suspected whenever a chronic ulcer with heaped-up or rolled-up edges is found in this region. More rarely, a basal cell carcinoma or malignant melanoma may be found in this region. The latter represents the most malignant of all colon and rectal tumors. It is rarely nonfatal. Ulcers suspected of being malignant should be widely excised and examined by a competent pathologist. If an invasive type of malignancy is detected, a radical combined abdominal-perineal resection should be done followed by a bilateral inguinal lymph node dissection and later a course of deep x-ray therapy. In cases where there is lymph node invasion the prognosis is usually very bad.

Benign tumors of the anal canal and perianal region are commonly encountered. Simple skin tags, papillomata, condylomata of various types and hypertrophied, fibrosed anal papillae are among those most frequently seen. The possibility of carcinoma in these lesions should always be kept in mind. Occasionally a low grade squamous cell carcinoma may be found in the periphery of a simple anal skin tag. Most of these tumors can be excised locally or destroyed by fulguration with a very low percentage of recurrences. Before disposing of them an adequate specimen should be sent to the pathologist for examination.

In examining the distal rectum with the index finger, tumors arising in the extra rectal structures should be carefully excluded. The prostate gland and seminal vesicles should be carefully palpated for nodules or irregularities. In the female the cervix and the base of the uterus and adnexa may be felt anteriorly to the rectum. Malignancies arising from these structures may directly invade the bowel wall.

Endometriosis may be detected in the rectovaginal septum as shotty nodes that are tender during menstrual periods. In exceptional cases endometriosis may invade the mucosa of the bowel and be indistinguishable clinically from carcinoma. Metastatic nodules from distant carcinomas may be felt anteriorly to the rectum in the peritoneal culdesac, forming the so-called Blumer's shelf. Masses palpated in the presacral areas are most often inflammatory in character but rarely teratomas, dermoids, chordomas or meningoceles may be felt. Other extrarectal nodules or masses include lipomas, fibromas, liomyomas or carcinoids. Usually these masses are found on routine examination or produce symptoms due to their bulk or in rarer instances

---

Presented at the Annual Meeting of the Southern Minnesota Medical Association, Winona, September 13, 1954.

Dr. Fansler is Clinical Professor of Surgery and Dr. Smith is Clinical Instructor of Surgery at the University of Minnesota.

produce erosion of the rectal mucosa or actually invade the lumen of the rectum.

Adenomas and carcinomas arising from the rectal mucosa will constitute the bulk of the tumors found in the colon and rectum. Adenomas may be sessile, papillary or pedunculated, single or multiple. They may measure only a few millimeters in diameter up to several centimeters. The smaller ones are more common and the surface of the polyp may be smooth, lobulated or ulcerated and may vary in color from the general appearance of the surrounding mucosa to a deep, dusky red. Occasionally a polyp may be attached high in the colon by a long pedicle and because of invagination of the bowel into the rectum or for other reasons prolapse into the rectum or even through the anal canal. This type of tumor may be difficult to demonstrate, particularly if the polyp returns high into the sigmoid colon on proctoscopic examination. Usually if the patient is asked to bear down during the examination, the polyp will once more prolapse to within range of the sigmoidoscope. Anesthesia is a detriment in attempting to visualize this type of tumor. The presence of induration, ulceration or attachment by a broad base of an epithelial tumor suggests the presence of malignancy.

If one polyp is found on sigmoidoscopic examination an air contrast barium enema should be done to rule out additional neoplasms higher in the bowel. Frequently a single polyp seen on sigmoidoscopic examination may be a satellite or sentinel polyp beyond which a frank adenocarcinoma may be growing. Approximately 20 per cent of the patients having polyps within the reach of the sigmoidoscope will have an additional one higher in the bowel. Polyps beyond the reach of the sigmoidoscope may be difficult to demonstrate with roentgenograms. A carefully done air contrast study may demonstrate tumors .5 cm. or even less in diameter. Before x-ray examinations are done the bowel must be thoroughly clean and free of fecal material. A careful air contrast study and a thorough fluoroscopic examination may have to be done repeatedly to detect the smaller tumors. A routine barium enema is usually inadequate in searching for colonic polyps.

A condition may be encountered characterized by several widely scattered polyps. These may extend at irregular intervals from the rectum cephalad to the cecum. If familial history exists with this condition it is commonly referred to as familial polyposis. Polyposis may follow chronic inflammatory disease of the colon such as chronic ulcerative colitis in which hypertrophied mucosal tags have formed a polypoid condition throughout the colon. At other times, without any hereditary or inflammatory background, several widely scattered polyps may be found throughout the colon. Carcinomatous changes are common in these cases. Multiple polyposis, regardless of the source of origin, is best treated by colectomy and ileoproctostomy. If carcinoma is found in the rectum, a combined abdominal-perineal resection must also be done and a permanent ileostomy established. Simple multiple colotomies with removal of individual polyps are not advisable unless a patient is a poor surgical risk.

Single polyps visualized from below should be biopsied either totally or by several adequate bites. The pedicle or base may then be fulgurated. If a superficial or non-invasive carcinoma is found, that is, one in which only the mucosa of the polyps is involved, thorough fulguration of the base will usually result in cure. Carcinoma which has penetrated the muscularis mucosa or muscularis should be treated by abdominal-perineal resection if in the lower two-thirds of the rectum, or occasionally by segmental resection and primary anastomosis if in the upper third of the rectum.

Biopsies and fulguration proximal to 13 cm. from the anal verge must be done with care to avoid perforation of the bowel wall. Lesions below 13 to 15 cm. can usually be fulgurated without danger of perforation except anteriorly where the peritoneal reflection in women may extend to within a couple of centimeters from the peritoneal floor. Single polyps beyond the reach of the sigmoidoscope are treated either by colotomy or segmental resection. If at the time of surgery the polyps appear to be flat, broad based and sessile, indurated or for any reason are suspected of being malignant, a segmental resection with excision of a broad wedge of mesentery is done. A small tumor on a long pedicle may be removed by simple colotomy and excision. We do not believe that segmental resection is necessary or advisable in all cases of a single polyp. However, if there is any doubt in the surgeon's mind as to the character of the tumor, segmental resection should be done. A frozen section should be made at the time of operation. While in many instances these examinations are inconclusive, there are cases in which a positive diagnosis of malignancy can be made. After the bowel is opened, a sterile sigmoidoscope should be routinely introduced to 25 cm. proximal and distal to the point of incision to rule out lesions beyond this point. The rest of the colon should be carefully palpated for additional lesions.

Frank carcinomas present in the rectum can easily be identified by their induration, rough, irregular edges and tendency to ulcerate. These are usually flat invasive lesions with a central ulceration and raised margins, but may be polypoid. The polypoid lesion may vary from a small tumor with malignant changes to large tumors completely surrounding and obstructing the bowel. Regardless of their clinical appearance they should be adequately biopsied. Preferably, the biopsy should be taken at the edge of the tumor near what appears to be the junction between the tumor and the normal bowel mucosa. Occasionally what appears to be grossly malignant may be diagnosed on microscopic examination as a simple infectious granuloma. Tumors lying in the lower two-thirds of the rectum should be resected by an abdominal-perineal resection. Tumors proximal to this in the upper third of the rectum may in some instances be removed by anterior resection and primary anastomosis. At least 8 cm. of normal bowel should be resected caudad to the tumor mass to accomplish adequate resection. Carcinoma of the sigmoid is usually removed by segmental resection, removing a wide wedge of mesentery and regional lymph nodes. A primary anastomosis is then done. Carcinoma of the descending colon and in the splenic flexure is resected by hemicolectomy and primary anastomosis. The same applies to cecal and hepatic flexure tumors. Tumors of the transverse colon are removed by wide segmental resection and removal of most of the transverse mesocolon.

A rare type of tumor which is occasionally found in various age groups is the villous papilloma. This tumor is characterized by its soft velvety appearance and many small finger-like projections. Usually it bleeds readily and secretes a large amount of mucus. These tumors are usually single and may be extensive enough to completely surround the entire bowel. About 10 per cent of these tumors are malignant and they should all be resected locally by the total biopsy method and thoroughly sectioned for evidence of malignancy. If malignancy is found it should be re-evaluated and a more radical procedure done. These tumors if benign on microscopic section are notorious for their tendency to recur locally.

Non-malignant tumors found in the colon and rectum include lipomas, fibromas, lymphomas, liomyomas and carcinoids. All of these are relatively rare. Usually they are felt as submucous tumors over which the mucosa is freely movable. They are easily removed by incising the mucosa and shelling out the tumor. They should all be subjected to microscopic scrutiny, and if any evidence of malignancy is found, a radical procedure is indicated.

Treatment of carcinoids is a matter of controversy. Up to 10 per cent of these tumors have a tendency to be invasive and metastasize. When these tumors are excised, a segment of the surrounding muscular coats of the bowel should be removed, and if on microscopic examination invasion is discovered, additional radical surgery is indicated.

Summary

1. A good digital and proctoscopic examination should be a routine part of all physical examinations.

2. Tumors suspected of lying above the reach of the sigmoidoscope should be investigated by thorough air contrast barium enema study with the x-ray and fluoroscope.

3. Most tumors lying in the rectum within the reach of the sigmoidoscope can be totally or adequately biopsied from below followed by fulguration of the base of the smaller ones. Microscopic study then should be the basis for further treatment.

4. Carcinomas lying in the lower two-thirds of the rectum are best treated by abdominal-perineal resection. Tumors lying above this area may be treated by anterior resection or segmental resection and primary anastomosis.

Topical Hydrocortisone in the Treatment of Skin Diseases

ROBERT W. GOLTZ, M.D.
Minneapolis, Minnesota

THE PURPOSE of this report is to review a year's experience with topical application of hydrocortisone in the treatment of various skin diseases. It is well known that the steroid hormones exert a beneficial effect on many inflammatory conditions of the skin. Unfortunately, their systemic administration is attended by not inconsiderable risk, and this risk is only occasionally justified. In contrast to its effectiveness in certain eye disorders, cortisone has been largely unsuccessful when applied to the skin. However, it has become apparent that topical hydrocortisone is much more effective than cortisone, and in fact makes a considerable contribution to the treatment of at least a few troublesome skin diseases.

Table I presents the results of hydrocortisone ointment treatment of 147 cases of various dermatoses. The cases cannot be said to be unselected, but because of the relative expense of this treatment, the cases treated tended to be difficult ones, often of long duration and unsuccessfully treated with many other preparations. The results are classified as 0, ±, no or virtually no improvement; +, minor or short term improvement only; + +, considerable improvement; + + +, great but incomplete relief, or complete relief which did not persist through the observation period; and + + + +, complete "cure", lasting throughout the followup interval. It will be noted that there are relatively few + + + + results, which indicates that hydrocortisone ointment is no panacea, but this should not be interpreted as too great an indictment of the drug, because many of the + + or + + + results represent considerable therapeutic success.

The patients with atopic dermatitis presented some of the most gratifying results. Past treatment of this disorder has been disappointingly unsuccessful, and many of the patients in this group had been to a very large extent incapacitated by their illness, as well as being disfigured and uncomfortable. The patients showing + + or + + + improvement, while not completely cured by hydrocortisone, were often improved to the point of being able to resume normal activities. Several volunteered the comment that this drug gave the most relief of anything they had ever used.

An example of a good result was a patient who had been hospitalized at least twenty times in the last nine years. He has now been working for ten months without interruption, the longest time he has ever put in on the job in his whole adult life. He is by no means free of eczema, but he is able to control it to the point where he is not incapacitated by it. Another patient in the + + + group has now used the drug for fifteen months, the longest of any patient in this entire series. Before starting the use of this preparation he was required to sleep with a wire mask on his face in order to prevent dis-

---

Presented as an inaugural thesis before the Minneapolis Academy of Medicine, April, 1954.

figuring himself by scratching in his sleep. His experience with compound F is interesting and presents some features common to many patients. When he first started its use, he obtained dramatic improvement. After three or four months, the drug gradually lost its effectiveness until the patient discontinued treatment. After another three or four months, during which time he tried several different remedies with poor results, he again tried hydrocortisone ointment. He has now used the drug in conjunction with a patent "softening" cream for over seven months, and remains in the best condition he has been in for twenty years. There is no present evidence of hydrocortisone ointment again losing its effectiveness. Several other patients in this group have also used hydrocortisone in conjunction with other topical remedies with apparent success, about which more will be said later.

The second group, though heterogeneous, represents some of the dermatologist's commonest and most difficult problems. It contains the chronic hand eczemas, and various chronic scaly inflammations which come under the heading of neurodermatitis, chronic contact dermatitis, or perhaps more accurately, eczema, cause undertermined. In general, the results in this group, though not spectacular, were good, considering the long history of unsuccessful previous treatment given by many of these patients. Here again, many of the patients were treated with combinations of hydrocortisone with other topical remedies such as tar, ichthyol, vioform, et cetera. The eight patients with seborrheic dermatitis did reasonably well. In latter months an ointment containing neomycin in addition to hydrocortisone was used and seemed to produce slightly better results in seborrheic dermatitis than hydrocortisone alone. It is commonly recognized that there is an element of at least secondary bacterial infection in this disease. In lichen simplex chronicus, hydrocortisone ointment was somewhat less successful than in other chronic inflammations. This is understandable, in that lichen simplex chronicus very probably is of psychic origin and no topical remedy could be expected to correct the underlying cause. It is interesting that in several instances, objective improvement in the lesions far exceeded subjective, in that the plaques lost their inflammatory character while continuing to itch.

In nummular eczema the results were good, and it is felt that hydrocortisone ointment makes a definite contribution to the treatment of this stubborn eruption. No effect was produced in an acute vesicular fungus infection of the feet, while an "id" eruption on the hands was benefited. The result in three cases of blepharitis of various causes was good.

The cases of acute dermatitis point up the weakness of this form of therapy as well as its strong points. Perhaps it would be well to discuss briefly the cases which were not helped. One was a patient with acute poison ivy eruption. Application of hydrocortisone ointment did not materially retard the development of the full-blown bullous reaction. Another patient was a florist who developed a severe dermatitis from chrysanthemums. She was unable to stop work and so continued contact with the offending allergen. Hydrocortisone application did not help her very much. Another similar patient was a farmer with a weed dermatitis on the legs. He continued to work and was not benefited by treatment.

On the other hand, those cases in which the causative substance was identified and could be avoided did much better. Illustrative cases included an acute dermatitis from contact with rubber, and another from adhesive tape. They recovered very quickly after discontinuing contact with these substances and the application of hydrocortisone. Admittedly, they would have gotten well anyway, but it seemed that their recovery time was materially shortened in comparison to similar cases treated by older methods.

The patients with pruritus ani, scroti and/or vulvae treated with hydrocortisone ointment were among the most grateful in this series. The results in these patients were strikingly good. An example is a man who had had pruritus ani since World War II. He had had a lot of treatment without much relief. He obtained immediate complete relief from his itching and gradual return of the skin to a normal appearance, and needs to apply the ointment only once every two to three days in order to remain completely symptomless. On the debit side, it must be reported that one patient who had good immediate relief noted a gradual decrease in results after five months' use, and finally discontinued using the ointment. It is interesting that, in this case, increasing the strength of the ointment from 1 to 2.5 per cent did not produce any better results. The one failure was a case of acute anal pruritus following the oral use of an antibiotic. This is the only patient with pruritus from antibiotics treated in this series, but at least one author has reported good results in similar patients.

Hydrocortisone topically may be said to be of little value in the treatment of psoriasis, lichen planus, discoid lupus erythematosus, rosacea and Darier's disease. The patient with psoriasis who was slightly helped was a patient with an acute irritative reaction in the anogenital area, such as is occasionally seen in "inverse" psoriasis. This irritation may be thought of as comparable to any other acute dermatitis. In this patient it was rapidly controlled by hydrocortisone, but the psoriasis itself was unaffected. The patient with lichen planus who was helped to some degree had a severely itching plaque over a pretibial surface. The itching was lessened considerably by hydrocortisone, and hence the irritation resulting from scratching, but the lichen planus itself was unaffected.

Contraindications

So far, no contraindications to the use of this ointment have been established. None of the patients in this series has been made worse by it. No sensitivity to topically applied hydrocortisone was observed or has been reported in the literature. The possibility of systemic effect from percutaneous absorption of hydrocortisone must be considered, but no evidence of it was observed, and it is almost mathematically impossible for patients using the amounts of drug used in this series to absorb any appreciable quantity of it. An experimental study has shown that topical application of extremely large amounts of hydrocortisone had no demonstrable effect on the circulating eosinophile count.

Another theoretical possibility is the spread of infection on the skin during the use of hydrocortisone. Actually no evidence of this was observed, though the ointment was not used in grossly infected lesions. To obviate this theoretical possibility, however, there is now on the market a combination ointment containing neomycin in addition to the hydrocortisone. This was used in several cases, and in at least two cases of seborrheic dermatitis (in which there is probably an element of infection) gave better results than the plain hydrocortisone.

In this series, combinations with other drugs were tried, including tar and ichthyol ointments and pastes, vioform ointment, et cetera. No attempt was made to compound these together, but the hydrocortisone ointment was applied first, massaged into the skin, and the other preparations then applied over it. In several instances these combinations appeared to give better results than either one of the pair used singly. This sequence was actually attempted in several instances.

There are now several brands of the ointment available. They differ only in the ointment base used, some being in a vanishing cream type base and others in a grease. Some patients expressed a preference for the grease base, others for the vanishing cream base. The grease base has the advantage of being somewhat less costly to use, in that it spreads more thinly on the surface of the skin, hence less is needed. To further confuse the issue, the ointment combination with neomycin is in yet a third type of base.

An objection to the use of this preparation which is always raised immediately is the great expense of the drug. Admittedly, it is expensive, and several patients have discontinued its use for that reason. On the other hand, the expense is less than it may appear, in that only very small quantities of ointment are necessary. The technique is to apply it in as thin a layer as possible and then massage it into the skin until practically none is left on the surface. This is necessary only twice a day, and sometimes even less often. Used in this way, the drug is pleasant to use and a 1 dram tube will last for several days or longer, even when used on relatively large areas of skin. This brings the treatment's cost down to a point where it compares not too unfavorably with that of many other medications. It is perhaps not widely enough appreciated how expensive practically all drugs are in the present age. Several patients volunteered the opinion that the cost of the ointment was well worth while in view of the benefit obtained. Certainly in the extreme cases in this series, particularly atopics, in which the patient was able to continue working and was spared the expense of hospitalization, the cost of the ointment was easily justified, even if necessary quantities cost several dollars a week.

There have already been several reductions in the cost of the ointment, and it is hoped that there will be more in the near future. Recently there has been marketed a 20-gram container which sells for roughly two and one-half times the cost of the 5-gram tube. This affords considerable saving to those patients requiring larger quantities.

An attempt was made to reduce the cost of therapy by making the ointment by grinding tablets of hydrocortisone and incorporating the powder in an ointment base. This reduces the cost of the actual material used about a third, but there is considerable labor required of the pharmacist, and there is further possibility that the resulting unsterile ointment may deteriorate rapidly. This technique is probably not justified except in large clinics where considerable quantities of the ointment are being dispensed within only a few days after preparation.

A final favorable factor in the cost of the ointment is that in almost all cases the 1 per cent ointment seemed to work about as well as the 2.5 per cent, at less than half the cost. In only exceptional instances was the 2.5 per cent definitely superior.

Summary and Conclusions

Ointments containing hydrocortisone were used in the treatment of 147 patients with a variety of inflammatory skin diseases. Results indicate that the preparation is of considerable value in chronic eczemas and in pruritus, but of little help in psoriasis, lichen planus, lupus erythematosus, et cetera.

Discussion

H. F. R. Plass, M.D.—I would like to compliment Dr. Goltz on this excellent paper and on his conservatism, both in the handling of the corticosteroid and in the interpretation of the results. This conservatism deserves to be emphasized so far as prescribing ACTH and cortisone, even when exceedingly small doses are used. A number of cases of Addisonian crisis have been reported precipitated either by surgical trauma or automobile accidents following the injection of as little as 25 mg. of hydrocortone into the knee joints. In the case of patients who have taken cortisone or ACTH, I believe it is more important that they carry identification than it is with the diabetic. This should take the form of a card in the billfold or purse, stating that these drugs have been used, so that if the individual is injured in an accident, necessary supportive measures may be taken to prevent these crises and probably death. This is more important for the ACTH or cortisone patient than it is for the diabetic, for the diabetic eventually identifies himself with a little sugar in the urine, while these patients simply go into shock and become edematous.

I. Fisher, M.D.—I agree with Dr. Goltz that there is much to be said for the use of hydrocortisone ointment in the chronic lichenfied dermatitis. This is particularly true in the case of the atopic dermatitis or in the sharply localized chronic lichenfied dermatitis. These appear to respond well to the use of hydrocortisone ointment in most instances. The ointment in itself is not a cure-all, nor does it clear all of these. It does, however, prove to be a very valuable adjunct in treatment and in many instances the only agent needed. I have not seen results quite as good as those Dr. Goltz has pointed out in some of these cases, but this may very well be a matter of individual interpretation and persistence in the use of the agent. I would certainly agree that there is a definite need for and room for the use of this preparation in the care of atopic dermatitis.

I do feel also that there is some difference in the results from 2.5 per cent hydrocortisone ointment compared to the 1 per cent and there are some instances when it does have its very definite merit and indications, particularly where the 1 per cent ointment has failed. One must admit also that the physical properties of an ointment are often as important as its specific therapeutic effect. That may explain the reason for the difference in the effect of hydrocortone ointment depending on the base in which it is incorporated. One may have to feel his way along here, using one type of base or the other in order to obtain the best results in the individual patient.

I have seen only two instances of any local irritation from hydrocortone ointment. These have not been instances of specific contact dermatitis but more apparent local irritation.

Another advantage in the use of the medication locally lies in the fact that then we may refrain from the use of such a potent agent systemically or at least to be able to cut down on the dose of this drug used systemically. It is our feeling that cortone or hydrocortone should be used very cautiously in the dermatologic patient, when it is administered systemically. There are not too many indications for its use in the acute or chronic dermatitis. We feel that this drug has been used somewhat loosely in the past and the time may come when we will have some repercussions from it. We cannot stress too strongly the need for caution in the use of this drug and for going without it whenever possible, particularly when local management will do a good job. This is especially true in the acute processes that will subside with good conservative management rather than with something as radical as ACTH, cortisone, or hydrocortone systemically.

A New Hydrocortisone for Intra-articular Use

PAUL J. BILKA, M.D.
Minneapolis, Minnesota

THE MAJOR limitation attending the intra-articular use of hydrocortisone acetate in rheumatoid arthritis is the relatively short duration of action of this drug. Although about 90 per cent of patients can expect significant local relief of symptoms within twenty-four hours following the injection of 25 to 50 mg. of hydrocortisone acetate into an actively inflamed joint, this relief usually lasts for only two weeks or less.[1,2] Occasionally the effect lasts as long as a month, and only rarely much longer.

In an attempt to obtain a more prolonged local effect from hydrocortisone acetate the author has studied several different methods of administering it.[4] Instead of the usually recommended dose of 1 to 1.5 cc. (25 to 37.5 mg.), patients were given 2 to 3 cc. (50 to 75 mg.) at one time. Although many patients obtained no greater benefit from the higher dose, in a large number local relief was prolonged by several days to a week or more. The author now makes it his regular practice to inject a minimum of 2 cc. (50 mg.) of hydrocortisone acetate into most of the larger joints.

A logical extension of this experience was the use of massive doses of hydrocortisone acetate intra-articularly. Approximately 100 injections of 125 to 250 mg. each were made into the knee joints of more than thirty patients. This study is incomplete but it appears that definite prolongation of benefit can be effected in many patients. There was no increase in adverse local reactions, and some patients showed systemic improvement for two to four days indicating probable absorption of the drug. Two patients, both of whom received three such massive injections, experienced "local remissions" in their knees. The "local remissions" have now continued for more than eighteen months despite the persistence of active synovitis in other joints.

A third method of attempting to prolong the local effect of hydrocortisone acetate involves the weekly injection, for a four to six-week period, of 1 to 2 cc. of the drug even though the joint remains asymptomatic. The majority of patients treated in this manner showed no cumulative effect. A few had relief lasting more than a month following the last injection, and one had a "local remission" of more than a year. One cannot help speculating as to the possible future replacement of surgical synovectomy by some chemical means.

Present Study

The present report concerns a less soluble ester of hydrocortisone, hydrocortisone-tertiary-butyl acetate, which was developed in the research laboratories of Merck and Co.* A preliminary report by Hollander et al[3] indicated that approximately 50 per cent of patients obtained better results with this compound than with ordinary hydrocortisone acetate, the duration of effectiveness of the new compound being two to ten times greater. Several other analogues of hydrocortisone which they tested showed no comparable superiority.

Thirty patients with rheumatoid arthritis were given, at different times and into the same joint, equivalent doses of hydrocortisone acetate and hydrocortisone-tertiary-butyl acetate. The local response was recorded in terms of the degree of improvement and its duration. The detailed data are presented in Table I. In no patient was the new compound less effective than hydrocortisone acetate. In five patients both drugs were equally effective. In the remaining twenty-five patients hydrocortisone-tertiary-butyl acetate showed some superiority. In eighteen patients this superiority was demonstrated by a longer duration of beneficial effect; in two patients by a greater degree of benefit; and in five patients by an increase in both degree and duration of local joint benefit. The average duration of relief for hydro-

cortisone-tertiary-butyl acetate was two to three times that of hydrocortisone acetate. No adverse reactions were encountered with either drug beyond the occasional (5 to 10 per cent) mild to moderate increase in local joint symptoms for four to 12 hours following an injection.

Osteoarthritis

As has been previously recorded by the author,[1] the chief usefulness of intra-articular hydrocortisone for degenerative arthritis is in the patient suffering from an acute or subacute exacerbation of his symptoms. Five patients with osteoarthritis of their knees were given injections of both hydrocortisone acetate and hydrocortisone-tertiary-butyl acetate with the results recorded in Table II. In one patient with chronic disability neither drug was particularly effective, but in the remaining four the new compound appeared to offer a significant advantage.

Shoulder Periarthritis or "Bursitis"

Due to the considerable day-by-day variation in symptoms, the high incidence of spontaneous improvement, and other factors, the evaluation of a therapeutic agent for periarthritis or so-called "bursitis" of the shoulder is beset with many difficulties. However, since the procedure is simple, safe and inexpensive, and with the belief that there is a logical rationale to its use, the author has adopted the practice of treating most of his patients with severe acute or subacute periarthritis by the localized infiltration of the injured and inflamed rotator cuff tendon with hydrocortisone acetate. Approximately 75 per cent of patients so treated have obtained 50 per cent or more relief of symptoms within twenty-four hours following a single injection. In addition to the relief of pain, the procedure has the added benefit of allowing earlier use of physical therapy for the correction of the contracted shoulder that occurs in so many patients.

Nine patients with acute or subacute periarthritis were treated with the local injection of 25 to 50 mg. of hydrocortisone-tertiary-butyl acetate. Two patients received little or no relief from the injections and the remaining seven obtained 50 per cent or more relief of symptoms. One patient who showed no relief following x-ray therapy the week before obtained a grade 2-plus response. Another patient obtained a grade 4 response within twenty-four hours whereas she had failed to benefit from x-ray therapy and two injections of hydrocortisone acetate given by her physician. From this limited group, however, it appears that the overall results with hydrocortisone-tertiary-butyl acetate are rather similar to those obtained with hydrocortisone acetate.

Summary

A comparison is made of hydrocortisone acetate and hydrocortisone-tertiary-butyl acetate when injected into the joints of thirty patients with rheumatoid arthritis. In 80 per cent of cases this new and more insoluble hydrocortisone ester demonstrated some superiority. This superiority was usually a prolongation of the local anti-inflammatory effect to two to three times that of hydrocortisone acetate.

Four of five patients with osteoarthritis of the knees showed a similar greater benefit from hydrocortisone-tertiary-butyl acetate.

Nine patients with acute or subacute periarthritis of the shoulder were given local tendon injections of hydrocortisone-tertiary-butyl acetate. Only one patient was also given hydrocortisone acetate, but when compared with previous experience with hydrocortisone acetate, the new ester appears to offer about the same degree of benefit.

WIDOWS

The number of widows in the United States increased by 90 per cent during the years between 1920 and 1953, while the adult population of women gained only 63 per cent. In 1953, there were almost 7.5 million widows in the United States. At present, one woman in every ten in the age group from forty-five to fifty-four is a widow, and the proportion is more than one in every four at ages fifty-five to sixty-four.

The recent increase in widows is apparently chiefly in the cities. The statisticians who are responsible for these figures believe that many widows in rural areas who do not remarry soon move to the city.

The importance of these statistics lies in the fact that widows inherit considerable assets and thus have a considerable voice in the economic affairs of the country. The problem is important because of the large number of dependent children left in the care of widows, and the relationship between broken homes and delinquency is clearly established. Another question is the disproportion in life expectancy of the male population to that of the female population which is so significant as to demand special consideration.—M. Fishbein: Editorial, *Postgraduate Medicine,* 17:338 (April) 1955.

Transplantation of Duct of Wirsung in Chronic Pancreatitis

LYLE J. HAY, M.D., and
FREDERICK OWENS, JR., M.D.
Minneapolis, Minnesota

CHRONIC relapsing pancreatitis constitutes a serious organic disease of the pancreas characterized by acute attacks separated by nearly complete remissions. Since the recognition of mild acute edematous or interstitial pancreatitis by Zoepffel[19] in 1922 and Elman[6] in 1933, and the introduction of a practical serum amylase test by Somogyi[17] in 1938, the clinical diagnosis of acute pancreatitis has been much easier and more common.

An unknown fraction of patients suffering from attacks of pancreatitis are destined to have recurrent attacks causing pancreatic dysfunction, such as diabetes mellitus, steatorrhea, creatorrhea, pseudocysts, severe abdominal pain and calcification, resulting malnutrition, anemia and drug addiction in about half the cases.[4]

Cause of Chronic Pancreatitis

Chronic relapsing pancreatitis appears to be repeated attacks of acute pancreatitis with resulting permanent changes in the pancreas. The cause of neither acute nor chronic pancreatitis is known. The most widely accepted theory is that of reflux of bile into the pancreatic duct due to impaction of a gallstone in the ampulla of Vater[14] or to spasm of the sphincter of Oddi.[1]

Other theories include (1) obstruction of the pancreatic duct from pancreatic sphincter spasm, pancreatic-duct calculi, epithelial hyperplasia, adenomas or strictures; (2) apoplexy from vascular closure or spasm; (3) trauma, including operations, and (4) infectious processes from mumps, scarlet fever or gallbladder infections.

Common-Channel Theory.—The basis for the common-channel theory rests on clinical, anatomic and cholangiographic data.

Clinical Data.—Clinical observations of the frequent association of gallstones or disease of the biliary tract with acute and chronic relapsing pancreatitis suggest either a causal relationship between them or that both diseases may be due to a common etiological agent or physiological arrangement. This association is well established.[7] Opie's common-channel theory has been the most broadly accepted explanation of this association.

Anatomic Data.—Dissection studies have revealed a common channel to be present in 4 to 70 per cent of persons. By injecting a test fluid into the common bile duct in fresh specimens after clamping the terminal 3 mm. of the duct, Hjorth[9] demonstrated a common channel in 86 per cent of 100 cases.

Since obstruction of the ampullae by stone with retrojection of the bile into the pancreatic duct was found in only 1.4 per cent of 437 cases by Guleke[8] and 4.4 per cent of 1,278 cases by Schmieden and Sebening,[15] this mechanism failed to explain the majority of the clinical cases.

Cholangiographic Data.—Widespread utilization of cholangiography in humans by Mirizzi[13] and numerous subsequent investigators had adequately demonstrated that sphincter resistance will convert the biliary-pancreatic ductal apparatus into a common channel in humans.

Howell and Bergh,[10] using pressures well within the range of the secretory pressure of the liver and pancreas and about 10 cm. of water above the patient's sphincter resistance, demonstrated the pancreatic duct in 41.5 per cent of cases. Significant was the fact that by repeated examination the pancreatic duct was visualized in fourteen of eighteen cases (77 per cent) in which clinical pancreatitis had been present and in thirteen of forty-seven cases (28 per cent) in which biliary tract disease had been present. Most important in their study, however, was the fact that elevations of serum amylase above control levels and out of the normal range occurred in both

---

Presented before the Minnesota Academy of Medicine, March 10, 1954.

groups in twenty-five of twenty-seven patients in whom filling of the pancreatic duct was demonstrated. Elevations of serum amylase occurred in only one patient in whom filling of the duct was not demonstrable. Attacks of acute pancreatitis lasting a few hours, three days and five days, respectively, were induced following cholangiography. The clinical diagnosis in these cases was established by the presence of pain and a persistent elevation of serum amylase. The pressures of injection were 30, 29 and 25 cm. of water respectively.

Bergh[2] stated, "We have supposed that such irritability (of the sphincter) is due to an inflammatory lesion (choledochitis secondary to stone)." Choledochostomy for prolonged periods (several months) has usually led to disappearance of the irritability. This sphincter spasm resulting in a common channel has been considered by Mallet and associates[11,12] and by Mirizzi[13] to be due to disease in the biliary tract or pancreas and by most writers,[1,3,5,9,18] to be the cause of biliary-tract and pancreatic disease. Resolution of this difference must await further investigative work.

Surgical Treatment of Chronic Pancreatitis

The surgical attack on pancreatitis based on the common-channel theory has been indirect. In cases with associated gallstones or nonfunctioning gallbladder[4,16] cholecystectomy, choledochostomy or choledochoduodenostomy has usually been performed. Since a considerable number of patients with pancreatitis are cured by these procedures, and to permit thorough investigation of the extrahepatic biliary tract and sphincter of Oddi and determine the presence of a common channel, my associates and I have performed choledochostomy with removal of the gallbladder if it were diseased. The choledochostomies were maintained for six to nine months, and if the sphincter resistance and the cholangiogram were normal, the tube was removed. Among twelve patients so treated one patient suffered recurrent attacks of pancreatitis after removal of the tube; three patients were admitted with recurrent attacks of pancreatitis after treatment elsewhere; in these patients common channels were demonstrated by cholangiogram.

Since in all these patients future health and life were threatened by their disease and because previous therapy had failed, interruption of the common channel between the common bile duct and the duct of Wirsung was decided upon. Division and reimplantation of the duct of Wirsung were selected to avoid the possibility of stricture of the common bile duct with resultant cholangitis. Division of the sphincter choledochus was not performed, as this therapy is under trial. The demonstration of contrast medium in the pancreatic duct in six of fourteen cases by Doubilet and Mulholland[5] also suggested that a more nearly complete diversion would be advantageous.

Four patients at the Minneapolis Veterans Hospital suffering from chronic relapsing pancreatitis have had division of the duct of Wirsung, near the ampulla of Vater; in one patient the proximal end of the duct was ligated, and in three patients it was reimplanted by suture anastomosis to the duodenum distal to the papilla. A fifth patient at the University Hospital has had division of the duct of Wirsung but the pancreatic end could not be located. The end of the duct toward the ampulla was ligated and an omental patch was sutured into the operative defect in the pancreas. An external fistula resulted and he continued to have pain.

Report of Cases

Case 1.—A twenty-eight-year-old man was admitted on September 10, 1948. Closure of a perforated peptic ulcer had been done in 1945. He had noted acute upper abdominal pain on August 8, 1948, after drinking beer. On August 22, exploration resulted in the diagnosis and external drainage of a pancreatic cyst. A wound separation and a "complete" external pancreatic fistula, resulting in hypokalemia, severe dehydration and weight loss, were present on transfer to our hospital. Rehydration, high-protein and high-caloric feedings and adequate electrolyte replacement brought about closure of the fistula, complete wound healing and a weight gain of 35 pounds at the time of discharge 28 days later. On November 16, 1948, he was readmitted with a new attack of pancreatitis and choledochostomy was done. Between this time and December, 1949, he experienced light attacks of pancreatitis, the last two necessitating multiple drainage of pancreatic abscesses. Subtotal gastrectomy in March, 1949, had not helped.

On February 10, 1950, division and ligation of the duct of Wirsung were done at its junction with the common bile duct. This patient has maintained his weight, has had normal stools and is able to work as a mechanic. He has returned on numerous occasions but has had no severe attacks of pancreatitis in the four years since operation. On six occasions elevations of serum amylase have been noted. He probably has low-grade recurrent pancreatitis. He suffers from recurrent insomnia and periods of mild depression, at which time he requests barbiturates and narcotics.

Case 2.—A twenty-three-year-old man was admitted on January 20, 1949. He was a moderate alcoholic. Choledochotomy and cholecystectomy had been done elsewhere in May, 1948, for cholelithiasis. The T-tube was removed in December, 1948, after which epigastric pain with extension to the left lumbar region occurred. He was admitted for study with severe epigastric pain. The serum amylase was 1,236 Somogyi units. After three days of failure of therapy, a mass developed. Exploration showed a large bile-stained edematous pancreas. A bile-filled abscess was present behind the head of the pancreas. Common-duct and retroduodenal abscess drainage was instituted. Nine days later an abscess in the right lower quadrant was drained. The choledochostomy tube was removed on September 30, 1949. He returned on February 19, 1950, with another very severe attack which subsided with use of gastric suction, splanchnic blocks and antibiotics. Since a common channel had been demonstrated by a cholangiogram, division and implantation of the duct of Wirsung was done on April 10, 1950. When last seen on September 30, 1950, he was asymptomatic.

Case 3.—A thirty-seven-year-old man was admitted on December 21, 1948. He was a bartender and a moderate alcoholic. Since June, 1948, he had had repeated attacks of epigastric pain, nausea and vomiting. A large epigastric mass with a pronounced bruit was noted in his epigastrium. Serum amylase studies were normal. On December 28, 1948, he was explored for pancreatitis with pseudocyst formation but only a chronically enlarged pancreas was found. Choledochostomy was done. Cholangiography demonstrated a common channel and caused an exacerbation of pain and increase in serum amylase. The T-tube remained in place one year, during which time he continued to have mild attacks of pain, nausea and vomiting. Four months after removal of the T-tube he entered another hospital with an attack of severe pain. This pain recurred twenty-four hours later and subsided after ten days of conservative therapy. He was transferred to our hospital in April and on May 10, 1950, transection and reimplantation of the duct were done. His postoperative recovery was uneventful. He suffered an attack of epigastric pain eighteen months later accompanied by albuminuria, hematuria and granular casts, with normal serum amylases on two occasions. A deformed spastic duodenal bulb was found on gastrointestinal examination. No definite diagnosis was established, though the presence of glomerulonephritis was likely from analysis of the record.

Case 4.—A thirty-one-year-old man was admitted on May 7, 1950, with a history of numerous attacks of epigastric pain for 2½ years. Exploratory laparotomy and drainage of the pancreas had been done in April, 1949. In August, 1949, splanchnicectomy, vagotomy and subtotal gastrectomy had been performed. The frequency and severity of the attacks were unaffected. On December 1, 1950, transection of the pancreatic duct with reimplantation was performed. One mild attack occurred two months after operation. None have occurred since. When last studied fifteen months after operation he was eating a regular diet, maintaining his weight and had had no attacks of pain. He had soft, formed stools which floated.

Summary

Ligation of the pancreatic duct was performed on one patient who had suffered ten severe attacks of pancreatitis over a period of nineteen months, with pseudocyst formation and complete external fistula on one occasion and pyogenic abscesses on two occasions. Previous drainage of the common duct and subtotal gastrectomy had failed to control the attacks. No severe incapacitating attacks have occurred since the ligation, though several mild ones have. No serious complications or evidences of pancreatic insufficiency have occurred in the subsequent four years.

Transplantation of the duct of Wirsung was performed on three patients, all of whom had symptoms of pancreatitis uncontrolled by other procedures, including choledochostomy in two and splanchnicectomy, vagotomy and subtotal gastrectomy in one. All three patients have had control of the disease process. In one patient, pancreatic insufficiency manifested by large soft floating stools developed.

Labyrinthine Hydrops

Ménière's Disease

CONRAD J. HOLMBERG, M.D.
Minneapolis, Minnesota

RECENTLY one of my colleagues said, "It seems to me that I am seeing an increasing number of patients presenting the complaints of dizziness and tinnitus—some with, some without the complaints of hearing impairment." He went on to say that he also felt an inadequacy about the treatment of this problem, especially for those patients with milder recurring symptoms not requiring hospital or bed care and who obviously seem to be in good general health. This led to an exchange of opinion in regard to possible factors that could explain an increase in incidence of this distressing triad of symptoms affecting the peripheral vestibular apparatus, which has long been known as Ménière's disease.

I feel sure that many physicians in specialties other than otolaryngology meet this problem very frequently and perhaps also sense an increase in its incidence. The demonstration of the histopathologic changes in the labyrinth which occur in Ménière's disease by Hallpike and Cairns[11] in 1938 served as a stimulus for greater study of this condition, and as a result the medical literature during the past decade abounds with contributions on the subject. Many studies confirm the histopathologic evidence of an endolymphatic distention of the cochlear duct without inflammatory reaction, with the result that the terms endolymphatic hydrops, hydrops of the labyrinth or labyrinthine dropsy are now commonly used to designate this disease. More and more evidence is accumulating to support the theory that an autonomic dysfunction or an intrinsic physical allergy can be the basic cause of this disorder.

Hilger[14] has shown that the vital intra-labyrinthine structures depend for the integrity of their function and structure upon end-arteries, without collateral circulation. This is true both in the cochlea and the vestibule. Disturbed vascular physiology common to all end-circulation can cause vasospastic changes in the labyrinth resulting in primary neurovascular ischemia and lymphatic hypertension to bring about this syndrome. Hilger claims spasm of branches supplying the cochlear ganglion cells results in tinnitus and hearing impairment in the frequencies involved. The frequent association of these symptoms with vertigo suggests involvement of the vestibulo-cochlear artery. Since extremes of physical and mental environment and psychomotor factors are chief causes of neurovascular disturbances, a modification in the way of our strenuous life and faulty living seems necessary in the prophylaxis and management of labyrinthine dysfunction. By this concept can we also point an accusing finger at the vasospastic effect of smoking as an additional contributing factor in recurrent ischemia of end-circulation? Do these factors then give some support and reason for our initial question of a possible increase in the incidence of peripheral vestibular and cochlear disturbances on a vasomotor basis?

Williams[25] theorizes that Ménière's disease is a form of intrinsic allergy involving the capillary loops of the stria-vascularis and that the endolymphatic distention is a localized extracellular edema produced by the spastic-atonic state of these capillaries.

Day[7] believes that in an occasional case a specific protein allergen may prove to be the causative factor and reports observations on several cases in which the symptoms could be abolished on removal of offending allergens only to recur with their reintroduction to the patient's environment. Day also believes and presents evidence that in labyrinthine hydrops the cochlea is primarily affected and the vestibular disturbances are due to secondary or overflow reactions of the vestibular mechanism. When the endolymphatic distention is limited to the ductus cochlearis, there will be no vestibular symptoms. It is probable then that distention of the utricle and saccule and membranous labyrinth producing vertigo occurs only

---

Inaugural thesis presented before the *Minneapolis Academy of Medicine* on December 15, 1952.

following an overflow of endolymph from the distended cochlear duct. This, according to Day, may occur with the initial disturbance, or it may be delayed for months or for years. When vertigo with nausea and vomiting in violent attacks are the prevailing symptoms, he suggests that they may be so incapacitating that they overshadow and submerge the more important cochlear symptoms of hearing loss and tinnitus which may have preceded vertigo for months or years. Day reviewed case histories of 220 patients which included 175 cases with the typical symptoms of vertigo, deafness, and tinnitus, and forty-five cases diagnosed as Ménière's disease without vertigo. A positive history of allergy was obtained in forty-five of the 175 cases of typical Ménière's and in twenty-three of the forty-five cases without vertigo. Twenty-seven of the 220 had bilateral involvement.

Boies[2] presented a study of the temporal bone and inner ear in a forty-seven-year-old man who suffered a fatal sub-dural hematoma when he fell during an attack of vertigo. A diagnosis had previously been made of Ménière's disease. Histopathologic findings in this case which were unrelated to his fatal illness revealed dilatation of the cochlear duct and degenerative changes of the spiral ganglion in the basal coil of the cochlea. This case had also been studied and reported by Lindsay[18] of University of Chicago.

From these and many other valuable contributions on the subject of peripheral labyrinthine dysfunction we now have available evidence that endolymphatic hydrops exists with or without vertigo. When vertigo is present to complete the syndrome of hearing loss with fluctuating tinnitus in recurring attacks, we recognize the clinical entity of Ménière's disease. From a review by Williams[24] of the original papers of Dr. Prosper Ménière on the subject which bears his name, it is obvious that this early physician and writer had a clear concept of labyrinthine lesions causing deafness, tinnitus, and vertigo with vomiting which previously in his day were considered symptoms of cerebellar or cerebral disease. This study also clarifies a universal misintrepretation, both in textbooks and papers, that Ménière believed hemorrhage into the labyrinth was the chief cause of the group of symptoms he described. Williams has shown that Ménière was intent on demonstrating to his colleagues that vertigo, nausea and vomiting need not necessarily arise from "lesions of the cerebellum or cerebral peduncles," but that when these symptoms are accompanied by deafness, the site of the disease lies in the inner ear.

The first microscopic observations of the temporal bones of persons known to have had severe attacks of vertigo, deafness, and tinnitus during life were described by Hallpike and Cairns[11] in 1938. These findings indicated a hydrops of the labyrinth, and it is reasonable to conclude that the effect of this hydrops on the cochlear duct, utricle, and saccule is responsible for the symptomatology. Because we have definite evidence of the etiology of this hydrops, the term idiopathic has been applied to this disturbance of fluid balance in contradistinction to that which has been found in association with inflammatory disease or vascular accidents of the labyrinth or pressure from central lesions.

Furstenberg[8] in 1934 reported observations suggesting tissue sensitization to the sodium ion as the responsible factor for the labyrinthine hydrops in Ménière's disease. Relief of symptoms was affected when retention of sodium was prevented and its elimination promoted. Investigations by Sheldon and Horton[22] in 1940 gave evidence that an alteration in the permeability of the capillary walls with secondary edema of the middle ear is a likely factor responsible for the hydrops and that histamine is an important agent in affecting capillary permeability.

More recently Lempert[16] and his co-workers have reported on the histologic changes in the inner lining of the membranous walls in the endolymphatic external semicircular canals of six patients with Ménière's disease who had partial labyrinthectomy performed for the arrest of vertigo. They found this inner membranous lining of all specimens to be studded with vesiculated epithelial excrescences suggesting the formation of epithelial fluid collections. They propose the theory that an attack of Ménière's disease is due to the rupture of one or more vesicles with release of a toxic fluid into the lumen of the endolymphatic membranous labyrinth. This is described as a chronic progressive herpetic neuritis. Lempert also postulates thatMénierè's disease may be primarily a disease of the vestibular labyrinth and that the cochlear pathology and symptoms are the sequela of the vestibular disease. They conclude that the cumulative loss of hearing during the course of the disease is due to progressive damage of the organ of Corti by the repeated contamination of the endolymph by this vesicular toxic fluid.

Symptomatology

The triad of symptoms in the usual case of Ménière's disease includes vertigo, tinnitus, and hearing impairment. The most constant symptoms are tinnitus, hearing loss in one ear and usually a sense of blockage of the affected ear. The auditory symptoms may appear at the same time as the vertigo or may precede it. In occasional cases there may be attacks of vertigo for weeks or months before auditory symptoms appear. The hearing loss fluctuates in degree with periods of regression, when the noises are also relieved, until the next cycle occurs. The loss may be progressive with each cycle. In the early stages the loss affects low tones primarily up to about the 4000 frequency. In late stages the entire tone scale is involved. Loss for bone conduction hearing parallels air conduction loss, suggesting a nerve type lesion but the fluctuation in hearing has been described as an indication of conduction rather than perception loss. Lempert,[16] however, claims the permanent loss in hearing must be considered a perceptive impairment. There is usually hypersensitivity to loud sounds, a phenomenon known as recruitment, which is notably absent in deafness due to a central lesion of the eighth nerve.

The tinnitus is usually described as a low pitched roaring, buzzing or seashell noise. It is the most variable symptom of the triad and its cause has not been established.

Vertigo may often be so disturbing that the patient is not aware of hearing loss. The attacks are usually explosive or paroxysmal, without warning and unpredictable in rapidity of onset, severity and duration. It may occur at rest, or even during sleep. Attacks may last from a few seconds to several hours or even days. Repeated cycles may go on for weeks or months with only mild periods of regression; secondary symptoms of nausea and vomiting are simply indicative of the severity of the attacks of vertigo. The patient usually describes his vertigo as a turning sensation in which he feels that he himself is turning or objects about him are whirling. He may have the sensation of being suddenly thrown to one side or in one direction. During intervals between severe acute attacks many patients have a constant feeling of unsteadiness and a vague sense of pressure in one ear or in the head. During these periods of remission the deafness, tinnitus, and hypersensitivity to loud sounds may persist.

In the diagnosis it is important to exclude chronic middle ear disease, lesions of the central nervous system, vascular changes affecting the auditory nerve, and toxic labyrinthitis with perceptive deafness and varying degrees of vertigo. In the latter bilateral involvement is the rule rather than the exception and the hearing loss affects the high frequencies more than the lower tone range. Vertigo in toxic labyrinthitis is often continuous and paroxysmal attacks rarely occur.

Caloric tests of labyrinthine function in Ménière's disease, as a rule, show diminished response or normal reaction from the affected side. Response from the two labyrinths may be equal but the test may often reproduce the vertigo described by the patient. The results of the tests are not diagnostic of Ménière's disease. Crowe[4] found that in 29 per cent of a series of his cases there was no reaction when the labyrinth of the affected side was tested. Day[7] claims a hyperactive labyrinth should never be found in a case of true Ménière's disease.

A word of caution is here in order when we speak so freely of Ménière's disease in association with such a common complaint as vertigo or "dizziness". Let us not narrow our thinking into using this syndrome or complex as the catch-all or mental shelf on which we place all vertiginous disorders just because there may be an associated hearing impairment and perhaps tinnitus; or when the patient has previously had such a diagnosis made either by himself or by another physician and received ineffective treatment for a peripheral vestibular disturbance. We must remember that organic disease of the central vestibular components especially in the brain stem and adjacent structures in the early stages may be manifested only by the classical signs of Ménière's disease. An organic lesion must be suspected especially when the labyrinth does not react to the caloric vestibular test. Functional ear examination may disclose a peripheral vestibular disturbance, such as in Ménière's disease, but more careful history, x-ray studies and vestibular tests, along with complete neurological analysis, may reveal a devastating tumor or cyst of the acoustic nerve in the region of the cerebellopontive angle. Dizziness may also be present in the course of acute or chronic middle ear suppuration with labyrinthitis, cerebellar disease, hypertension and cardiovascular disease, toxic vestibular neuritis, and in many other general systemic infections.

Treatment

Both medical and surgical treatment are in current use. It should be stressed that conservative medical therapy should be instituted as early as possible in all cases suspected of Ménière's disease. If hydrops without vertigo is suspected, early treatment may retard or prevent the onset of vertigo. The longer the symptoms have persisted, the less effective is conservative medical treatment. Day[7] claimed restoration of practical hearing and relief from tinnitus in about one-half of his cases without vertigo when treatment was begun during the first year following onset of symptoms.

These patients are usually victims of tension and anxiety states. The physician must express utmost sympathetic understanding of their complaints. All deserve a careful complete physical examination, including a neurological study when any doubt exists as to the cause of the vertigo. They should be told that recurrences in symptoms are to be expected, and they must be encouraged to live a more quiet and regular life. Mild cases are benefited and often controlled by use of sedatives. Williams[25] stresses treatment of the anxiety state by discussion, explanation and relaxing physical therapy.

On the basis of vasomotor phenomenon with increase of capillary permeability resulting in disturbed water metabolism, Mygind and Dedering[19,25] recommended a low salt diet, limitation of fluids to 700 cc. daily or to a point of conscious thirst. Salt restriction promoted diuresis. They also advised laxative salts, a reducing diet for overweight patients, and a high caloric diet for the underweight. Physiotherapy was given to improve vasomotor function.

Furstenberg[8] and co-workers have recommended a sodium-free diet along with ammonium chloride in dosage of 6 to 9 gm. daily for alternating three-day periods. The course of treatment lasts six weeks. A high potassium diet has been used by Talbot and Brown[23] with favorable results. They used 6 to 10 gm. of potassium chloride in solution daily.

The use of histamine by intravenous injection has been recommended by Sheldon and Horton[22] for relief of an acute attack of vertigo. Lillie, Horton and Thornell[17] reported improvement in hearing and relief from vertigo by intravenous histamine injections daily for three to six days and sometimes longer. They have used 2.75 mg. of histamine acid phosphate in 250 cc. physiological saline solution or in 0.8 per cent potassium chloride solution. The fluid is given at a rate of 20 to 60 drops per minute over a period of about one and one-half to two hours.

The use of nicotinic acid has been recommended by Atkinson,[1] Williams[25] and others. The action is attributed to the vasodilator effect of the drug rather than that of a vitamin. Atkinson[1] claims that one group of cases responds to histamine desensitization and one group to nicotinic acid, distinguishable by an intradermal histamine test. For the nicotinic acid group he gives daily intramuscular injections of 10 to 50 mg. or oral administration of 50 to 150 mg. per day for several months. Williams[25] advocates vasodilators alone for those cases of Ménière's disease without endolymphatic hydrops (recurring attacks of vertigo without tinnitus or deafness) on the supposition that vasomotor labyrinthine ischemia alone is present. He uses nicotinate (Nicamin) subcutaneously and nicotinic acid or Roniacol orally. When symptoms of hydrops (deafness and tinnitus) are present along with vertigo, he combines the effect of vasodilators to correct the arteriolar spasm with a low sodium diet for elimination of fluid collection in the endolymphatic system. He allows 0.5 gm. of sodium per twenty-four hours. A modified Schemm diet seems to meet his requirements. This is not only a low sodium but an acid to neutral-ash diet. A moderate restriction of fluid to a total intake of 3,000 cc. is advised.

Several drugs have been used for relief of or preventive effect on vertigo. These include adrenalin, atropine, pilocarpine, estrogens and thyroid therapy, diethylstilbesterol, Banthine as ganglion blocking agent on the parasympathetics, iodides, papaverine, and tetra-ethyl ammonium chloride (Etomon) for its blocking action of autonomic impulses at the synapses in both sympathetic and parasympathetic ganglia. The latter may produce severe postural hypotension, and the drug must be given with caution in patients with hypertension.

On the basis of Hilger's[13] hypothesis that Ménière's disease is due to autonomic labyrinthine ischemia and the production of a neurovascular spastic state in the vascular bed of the labyrinth, he directs the therapy at correction of the vasospasm and the resorption of transudates. He believes this is best accomplished in an acute vasospastic crisis by a neural block rather than generalized vasodilatation alone, and the most effective method of increasing local blood supply is sympathetic denervation of the part. He proposes a combination of a neural blocking agent and a peripheral vasodilator that would increase the heart action and total blood volume as the most ideal and effective approach. For this he uses an infusion of 0.1 or 0.2 per cent procaine hydrochloride solution in 5 per cent glucose. To 1 liter of this solution he adds 0.1 mg. of adrenalin hydrochloride and 1 gm. of ascorbic acid. This is given intravenously in daily treatments of 250 to 500 cc. over a period of one and one-half to two hours. Hilger considers the beneficial effect of this therapy is due to a continuous blockade of the cervical sympathetic ganglia. No evidence of toxicity or sensitivity has been reported by him. In the writer's experience this treatment has produced favorable results in reducing the severe acute vertiginous attacks as well as restoring some degree of hearing loss in many cases presenting this syndrome.

Because of the known toxicity of streptomycin on the vestibular end-organ, this medication has been used by intramuscular injections to destroy the labyrinthine function in selected cases of severe and disabling vertigo. Hanson[12] reported good results in eleven cases and offers the hypothesis that there is a selective neurotoxic action of streptomycin on the altered (diseased) labyrinth or on the vestibular pathways in endolymphatic hydrops. He has used injections of 2 gm. daily over a period of three to five weeks and with this dosage found no significant effects on cochlear (hearing) function. Glorig[9] reported 31 per cent of patients with tuberculosis showing hearing loss when treated with dihydrostreptomycin in doses of 2 to 3 gm. daily for three months or more. It is obvious that purposeful streptomycin destruction of the labyrinth should be limited to well-selected cases which have had careful otologic and neurologic study and evaluation.

Adequate rest and regularity in habits of work and activity must be stressed in any plan of therapy. Psychotherapy and various forms of physiotherapy are of prime importance, for in many cases the onset of attacks can be traced to emotional upsets or mental and physical fatigue.

If conservative medical therapy fails to control the attacks of severe vertigo in Ménierè's disease, surgical intervention is indicated. Hearing is not improved by surgery and its effect on tinnitus is variable. Surgery should be limited to the case of unilateral involvement with severe hearing impairment. Day[5,6,7] advocates surgery when the attacks of vertigo occur without warning and are so severe that the patient falls when engaged in an occupation where a fall might endanger his life or if he lives in constant fear of impending severe attacks. Two main types of operative procedures have been advocated.

1. Partial or complete section of the eighth cranial nerve, as described by Dandy, is still practiced by some neurosurgeons. Partial section theoretically is the ideal procedure in that the remaining hearing is preserved to some degree in about 40 per cent in several reported series by Dandy and co-workers.[10] This is a major neurosurgical performance attended by some risk of intracranial complications. Tinnitus has been relieved in only about 50 per cent of cases undergoing this treatment. Day maintains that if partial section be performed with preservation of hearing, there is likely to remain a preservation also of some vertigo.

2. Several procedures attack the membranous labyrinth directly. Portmann[21] describes a destructive operation on the endolymphatic sac. Recurrence of symptoms following this procedure is common. The operation in general favor today is one employing an opening into the labyrinth by way of a mastoid approach to destroy the labyrinthine end-organ. Cawthorne[3] removes a piece of the membranous external semicircular canal or merely makes a tear in it. Day[5,6,7] opens the external semicircular canal and coagulates the vestibular contents with a weak diathermy coagulating current. Other operators have destroyed the contents by inserting a barbed dental hook into the vestibule. This is a relatively simple procedure in which there is a possibility of preserving some degree of the residual hearing. At the present time Day no longer attempts or advocates differential electrocoagulation because of his poor results when hearing was preserved and because of added possibility of incomplete destruction of the vestibular mechanism. The period of hospitalization and rehabilitation is much less with the Day operation than with the more difficult operation of total or partial nerve section.

Recently Passe and Seymour[20] have reported favorable results with a procedure consisting of removal of the stellate ganglion on the affected side, division of T_1 and T_2 and stripping or section of the vertebral artery.

Lempert[15] has also recently described a decompression of the hydrops of the endolymphatic labyrinth with degeneration of the labyrinth and organ of Corti by removal of the stapes and round window membrane.

These intralabyrinthine surgical procedures in their present stage provide relief from severe vertigo in Ménière's disease, and although they give a poor prospect for preservation of hearing, they are meeting with preference because of relative simplicity and safety from complications.

Summary

1. Abundant reports in recent years on the study of Ménière's disease reveal an almost universal conception that this common disorder of vertigo, hearing loss, and tinnitus is probably caused by an autonomic nervous system dysfunction or intrinsic allergy, producing a neurovascular spastic state of the labyrinthine circulation and resulting in endolymphatic distention or hypertension.

2. Intrinsic emotional stress related to the extremes of physical and mental environment in our strenuous life may be the chief factor in precipitating neurovascular disturbances of the labyrinth. Heredity and physical factors also have great significance. A specific protein allergen may prove to be causative factor.

3. Hydrops of the endolymphatic system may exist with or without vertigo. The effect on the cochlea with hearing loss alone may be the primary disturbance, and it may precede any disturbance of the vestibular mechanism by a period of months or years.

4. Conservative medical treatment can relieve and control the acute vertiginous episodes in the majority of cases of Ménière's disease. When therapy is instituted early, a fair prognosis in restoration of hearing loss can be anticipated. Recurrences must be expected, and the patient should be encouraged to live a more regular life with emphasis on the avoidance of stress and tension states. A sympathetic understanding of symptoms by the physician and psychotherapy play an important role in the regulation of emotional stress.

5. The possibility of an organic central nervous system lesion must always be considered when vertigo is of long standing and persists with progressive loss of hearing or when proper medical treatment fails to bring about remission of symptoms.

6. Surgical destruction of the membranous labyrinth by several methods of labyrinthotomy provides relief of severe vertigo in unilateral Ménière's disease and appears to be the treatment of choice when proper medical management has failed and hearing function is severely impaired.

Visual Problems of Patients Who Have Unilateral Cataract Operations

E. S. PALMERTON, M.D.
Fergus Falls, Minnesota

OPHTHALMOLOGISTS are often called upon to attend patients who must either consider removal, or actually undergo removal, of a cataract from only one eye, while the other eye is still capable of considerable vision. The purpose of this article is to inform doctors who do not work regularly with optical problems, about the perplexing visual difficulties of these people.

Removal of the lens from an eye radically changes its optical mechanism.[4] In the first place the eye is made very far sighted. To restore good vision after operation, in almost every case a lens of high plus power, in the range of plus 9. to plus 12. diopters must be prescribed, along with a variable amount of cylinder to correct the astigmatism resulting from the healed incision. A lens of this power is unavoidably heavy and the spectacle frames are easily bent out of adjustment. A distorted image results when the wearer looks elsewhere than exactly through the center of such a lens. In addition, the periphery of such a lens creates so marked a prismatic effect that the wearer has a ring scotoma of considerable width.

The power of accommodation is of course lost from an aphakic eye. Another important effect is the magnification of the image seen with such an eye, an image in most cases 25 to 30 per cent larger than that seen with a normal eye. The amount of aniseikonia (unequal image size) varies, depending on the distance in front of the cornea at which the glasses are worn. This large imagery is the result of the removal of the lens from within the globe and the substitution in its place of a strong plus lens in spectacles.

As may be imagined, the reactions of various patients to such a situation differ widely.

If the vision in the lensless eye is good and that in the untouched eye definitely down, the shift over to the aphakic vision will be made more or less smoothly in the course of some weeks—in general, the older the patient, the slower and more discouraging the period of relearning. If the normal eye still sees well, most patients, both young and old, will choose to see with it and will ignore, or try to ignore, the image seen with the aphakic eye. In a child this usually amounts to prompt suppression. In an older person the unnatural image is likely to be troublesome. To avoid it, the patient may close his aphakic eye, wear an occluding device such as a rippled lens, or even a patch. It may be sufficient merely to let the eye go uncorrected. In rare cases a patient is able to tolerate the marked inequality of image size and seems happy with full correction for each eye. However, on careful questioning it will usually be found that he is suppressing one of the images for the everyday, ordinary conditions of seeing.[7]

This inequality of image size may be cut down to about 10 per cent by providing the correction for the aphakic eye as a contact lens.[2,6,11] Some aphakic patients can tolerate a contact lens for a surprising number of hours. This is a clever and often quite satisfactory solution for the problem in patients who want binocular vision. The eye so corrected, however, is still unable to accommodate, and for near vision a spectacle lens with a bifocal segment is necessary in addition to the contact lens.

The best description the writer knows of, concerning aphakic vision, is in an editorial by an anonymous ophthalmologist in the *American Journal of Ophthalmology* for January, 1952.[1] In it are colorfully described the surprising magnification of images, the disturbed ability to judge distances, the field limitation and the distortion: bulging door frames, weaving pillars and walls, and so on.

Readers of this article who want to experiment with unequal image size can easily do so with the lenses in an ordinary trial case. This may be done with glasses on, or if no glasses are worn, with the trial frame.

If a trial frame is used, the cells in front of the right eye are left empty. A minus 20. D lens is put in the left back cell, or better yet the lens is held very close to the left eye. This artificially makes the left eye very far sighted. Now a plus 16. D lens is put in the farthest front cell on the left side. If glasses are worn, the same two lenses can be used, the minus lens held behind the glasses very close to the eye, the plus lens in front of the left spectacle lens. The vision of the left eye will clear, but at once it will be noted that the left eye is seeing images distinctly larger than those seen by the right eye. This inequality is of the order of about 10 per cent, and fusion of such images is readily done by many people. If more attention now is paid to the image seen with the left eye, considerable peripheral distortion will also be noted.

This arrangement of lenses is merely a Galilean system. The writer does not mean to imply that this experiment makes the phakic eye see like an aphakic eye. It does not. But it does provide an easy demonstration of rather marked aniseikonia, and of the distortion suffered in looking through the peripheral part of a thick lens.

It now becomes easier to understand the complaints of a senescent patient who is suddenly confronted with a new kind of vision through glasses two or three times as thick as any he ever wore before.[3,9] Furthermore, it is no wonder the problem is magnified when an attempt is made to team up this new vision with that of a phakic eye. If the ordinary eye affords even partly satisfactory vision, the patient will often choose to disregard the function of the lensless eye as best he can, even though the aphakic image, on Snellen testing, may be considerably sharper than he can possibly get with the other eye. Anticipating such difficulties, an eye surgeon will often decide against operating upon a unilateral cataract, but will send the patient home to wait until the vision in the better eye is such that there can be no argument about operating. It is no longer wholly a question of waiting until cataracts are ripe. It fact removal of mature cataracts has certain disadvantages that will be mentioned. But often a cataract may remain in an eye for years without causing harm, and until the better eye is reduced to correctible acuity of 20/60 or even worse, the eye surgeon may prudently advise delay.

There are certain risks to be considered in such delay. Some eye surgeons state that an eye with a mature cataract in it should have surgery if the patient is physically able.[8] The principal reasons for this opinion are:

1. One never knows just what is going on behind a cataract (possible tumor).
2. As time goes on a cataractous lens tends to grow firmer and its removal intracapsularly is more difficult.
3. Occasionally a cataractous lens may enlarge enough to cause secondary glaucoma, or breakdown products from the degenerating lens tissue may cause an irritable eye or even a disastrous inflammation.
4. Divergent strabismus of the non-seeing eye often occurs.

The first three of these complications are not frequent. Ophthalmologists have all watched, for years, numbers of aged patients with cataracts in one eye, or cataract more advanced in one eye than in the other. For one reason or another surgery may be refused or postponed, and many such old people will live out their life spans without having to submit to intraocular surgery at all. Such patients should be seen periodically to watch for complications. A cataractous eye will not become amblyopic except in a child. It may be argued that it is probably safer for a patient to undergo surgery earlier in life if he must eventually have it anyway. But it is not certain he will have to have it eventually, and the early ambulation now used after eye surgery, together with the almost universal employment of corneoscleral sutures, makes this argument less compelling.

A patient in young adult life or middle age has a different problem. The likelihood of divergent strabismus developing needs serious thought. Younger patients often need the peripheral vision on the side of the cataractous eye, or a man may have a job for which binocular vision is important. Here the cataract may be removed, and if the patient wears no aphakic correction at all, he at least gets a field on that side, though badly blurred. He may try the full correction for each eye—rarely is a patient happy with this. Or the scheme of the contact lens for the aphakic eye may be used.

The Ridley operation for cataract consists of extracapsular extraction with insertion of an acrylic lens into the eye to take the place, both optically and actually, of the original lens. It was conceived and developed to avoid the visual difficulties that patients have after ordinary cataract surgery. It is too early for the eventual fate of this operation to be known. However, many eye surgeons are voicing unfavorable opinions about it, the reason being that a large proportion of cases react to the presence of the foreign material within the eye.[5]

Lastly, unilateral cataract may be seen in a child, either from a congenital cause or as a result of any eye injury. Here the problem of amblyopia is added to the already complex situation. If the child is an infant, the amblyopia will be one of arrest; that is, the vision is not having a chance to develop and it will not subsequently develop, unless a reasonably clear image be provided for the macula by the time the patient is from one and a half to two years old. Surgery for congenital cataracts sounds simple—needling the lens and letting it absorb. But the operation has hazards and more than the procedure itself must be considered. Many infant eyes with congenital cataracts present other defects. If surgery is successful, the strong aphakic correction must be provided for the tiny patient if vision is to develop. The proportion of surgical failures is considerable, and in later years retinal detachment may occur, nullifying everything.[10] Therefore if the other eye is normal the surgeon may advise against operation.

An older child who develops a cataract after the years of his infancy may also get an amblyopia in this eye—but it will be an amblyopia of extinction, and vision can be regained if loss of the other eye should make it necessary. The cataract can be removed by needling, or by linear extraction, and the eye will probably not be used, even if corrected, unless vision in the fellow eye is poor. A contact lens for the aphakic eye would seem ideal, but Goar states he has never seen a patient under eleven years of age who would tolerate one.[8]

Giant Condyloma (Verruca) Simulating Carcinoma of the Penis

ISADORE FISHER, M.D., and
C. F. HAAS, M.D.
Minneapolis, Minnesota

GENITAL WARTS (condylomata acuminata, verruca acuminata) are to be found in both sexes. Condylomata are elevated, circumscribed, papillary masses that occur most commonly on moist cutaneous and mucocutaneous surfaces. They are to be seen on the genital and anal regions where the surfaces are moist and exposed to friction. Irritating discharges and secretions create an improved medium for their growth. Both the appearance, and shape of the verrucae appear to be influenced by their location as well as by the trauma that occurs associated with the location. The verrucae are usually elevated, circumscribed, papillary masses. They may resemble great masses of granulation tissue. On the male genitals, especially around the corona, one sees the more filiform type of lesion. The lesions may be isolated excrescences, or may be in small groups or even in large verrucous masses which mask normal structures. The appearance on the female genitals may be that of an enormous granulation tissue with cauliflower-like appearance. On the female genitals, the involvement is on the labia with some concentration around the entroitus. Condylomata may also occur about the face, around the mouth, the axillae, and in the periumbilical region. Extension as well as growth is limited principally to the warm, moist regions.

Like all types of warts, condylomata acuminata are autoinoculable and transmissible. The transmissibility was demonstrated long ago by Jadassohn and others. Rulison in a statistical study emphasized the higher incidence in certain families.[11] It has been shown that some patients with condylomata acuminata on the genitals have verrucae vulgaris on their hands. Recently Barret et al emphasized the reclassification of genital warts as venereal warts. They pointed out the ease and frequency of transmission from one individual to another through intercourse. Rhodes reported experimental transfer of human wart material to a monkey's prepuce.

As far back as 1919, Wile and Kingery discussed the etiology of common warts.[16] Kingery later was able to take material and reinoculate warts from the second generation in order to point out that the virus was viable and transmissible. Goodman and Greenwood[6] were able to produce verrucae vulgaris and verrucae plana from material taken from condylomata acuminata and filiform warts, thus leading to the feeling that all verrucae have a common etiology. Verrucae plana have also been demonstrated from material taken from laryngeal papillomata. The contagiousness of warts and condylomata has been definitely established by observation of accidental transmission as well as by experimental transmission carried out through inoculation of finely ground material. Wilson suggested the term genital warts rather than the term condylomata acuminata and felt that it was a better and more descriptive term.[17] He noted that the growth of condylomata increased considerably during pregnancy possibly due to the stimulating action of estrogen. Attempts have been made to incubate the verruca virus on rabbit and mouse brain but they have been unproductive of any results. On the other hand, inoculation of material in rabbit testicle produced inclusion-like bodies (eggs later inoculated from testicular material were negative). Wilson unsuccessfully attempted to inoculate chorioallantoic membrane. Felsher[3] also inoculated chorioallantoic membrane of the chick embryo with material derived from verrucae vulgaris and was unable to demonstrate any satisfactory growth. It was his opinion that no definite conclusions could be drawn concerning the possible

---

From the Department of Dermatology, University of Minnesota. Henry E. Michelson, Director.

Presented at the Annual Meeting of the Southern Minnesota Medical Association, Winona, Minnesota, September 13, 1954.

Dr. Fisher is clinical assistant professor, Dermatology and Syphilology, University of Minnesota Medical School.

Dr. Haas is a Fellow in Dermatology and Syphilology, University of Minnesota Medical School.

virus etiology of skin diseases by negative results in the inoculation of the chorioallantoic membrane. He felt that the chorioallantoic membrane in seven to fourteen-day-old chick embryo was unsatisfactory material for culturing dermatotropic viruses. Recently, Bivins was able to inoculate material obtained from verrucae vulgaris into chorioallantoic membrane.[2] It was reported and illustrated with material that has been carried through a Berkefeld filter producing massive proliferation and "pearl" formation on chorioallantoic membrane.

Much work has been done in demonstration of the inclusion bodies as found in warts. Lyell et al were able to demonstrate eosinophilic intranuclear and intracytoplasmic bodies in the prickle cell layers of some warts. The inclusion bodies varied considerable in size and shape. Not all of the prickle cells were involved in the process.

Blank reviewed the virus etiology of verrucae.[1] He agrees with Lipschultz that the inclusions are basophilic and intranuclear. Blank examined about 150 verrucae from sixty-five patients, six of whom had condylomata acuminata. He concluded that pathognomonic changes occur in the nucleus in such a manner that basophilic material eventually fills and distends the nuclear membrane. About half of all verrucae examined contained cells with the inclusion material. The material contained large amounts of nuclear protein, most of which appears to be desoxyribose in form.

Strauss demonstrated spherical virus-like particles which tended to aggregate in regular nests in papillomatous growths of human skin.[14] They all had a similar histologic appearance. They were intranuclear inclusion bodies with solid or vacuolated masses in the cytoplasm of the rete cells. The growths seemed to be the same in verrucae vulgaris as in verrucae plantaris. This crystalline material that was demonstrated appeared to represent the first crystalline material isolated from human growths.

The above listed information helps link condylomata with verrucae vulgaris and makes for a common demonstrable virus etiology. The different behavior of the virus at the various sites is not so readily explained, particularly when the growth becomes extensive, bizarre in character, or destructive. Usually when condylomata acuminata are seen in the male, they occur on the inner surface of the prepuce along the coronal margin or on the glans penis. The prepuce, with the accumulation of moisture and secretions under it, predisposes to the formation and localization of genital warts. They are small and usually remain confined to the named area. There is, however, one uncommon form of giant condylomata which grows extensively along the prepuce, sometimes perforating and destroying this structure. They may also grow over the glans, destroying it, producing distortion of the penis and in that manner giving the entire growth the appearance of a malignant neoplasm. The lesion is malignant locally by virture of the destruction it produces. Microscopically it appears to be benign. The uncontrolled growth and destruction produces ulceration, involves normal structures and frequently fosters secondary purulent infection. This infection adds to the foul odor produced by the growth.

The giant destructive condylomata were originally described by Buschke. Later they were discussed more extensively by Buschke and Loewenstein, both of whose names are now linked with this type of tumor.[9] Loewenstein made the first report in the American literature in 1939 when he reviewed the literature and described a case. In his description of the histology the stratum germinativum and spinosum remain clearly demarcated and show no evidence of any malignant change in spite of all the marked proliferation. This indicated definitely a benign lesion that for some reason became markedly proliferative. There is a tendency to infiltration deeper into the tissue layers of the penis. There is no sign of malignancy aside from this excessive growth. There were mitoses to be seen in epithelial layers, but there were no glandular metastases. It was Loewenstein's opinion that the growths developed in a preputial cavity which was constrictive and that the break occurred into the prepuce and then through it, perforating the structure.

Gersh reported two patients with similar destructive lesions.[4,5] In both cases the lesions occurred in individuals who had a phimotic prepuce. It was Gersh s conclusion that early complete removal with circumcision should obviate the necessity of radical procedures later on. Numerous writers have raised the question as to whether these condylomata should be considered pre-

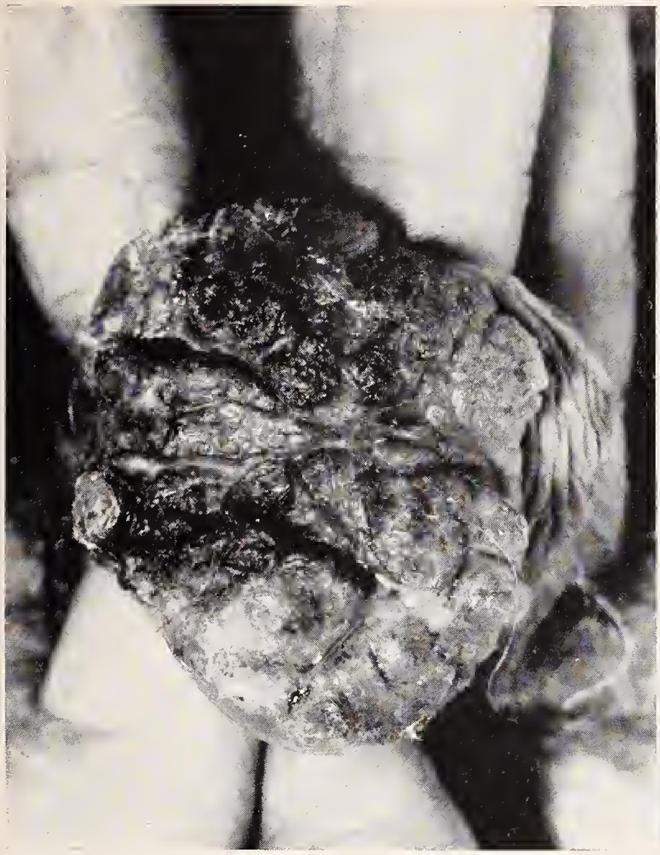

Fig. 1. Case 1, E. D. B. Large, vegetative verruca involving and destroying the glans penis. Biopsy specimen revealed benign condylomata.

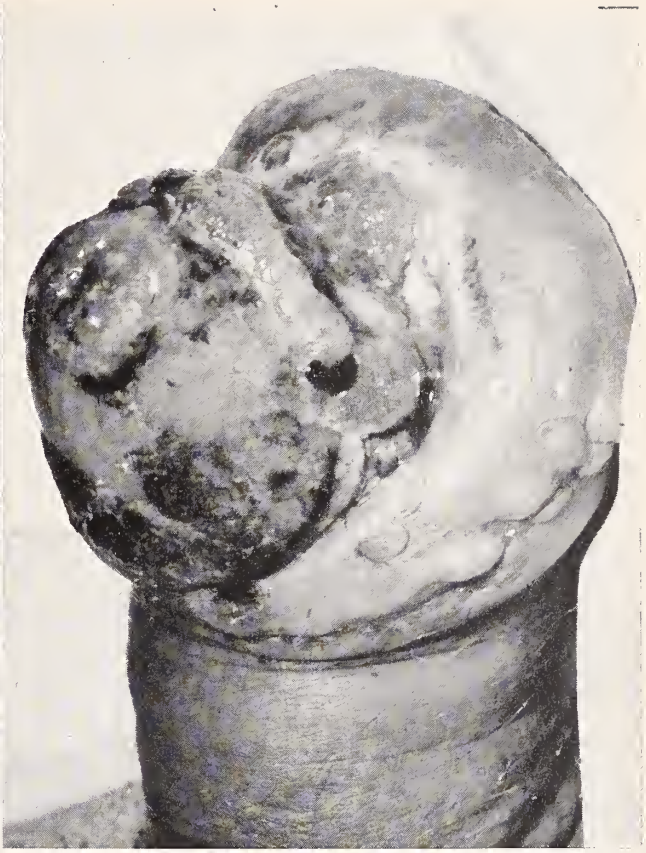

Fig. 2. Case 2, T. A. Verrucous growth seen on the glans, at the corona and involving the prepuce. Shown after drainage of abscesses and dorsal slit.

cancerous and the suggestion has been made that repeated biopsies be carried out in order to rule out this possibility. The therapy would hinge on the accurate diagnosis.

Various forms of therapy have been suggested for condylomata acuminata and particularly the ones of this type. In 1942 Kaplan[8] described the use of the resin of podophyllin in the destruction of acuminate warts. His original treatment has since been modified somewhat so that the tincture is used instead of a suspension of podophyllin in liquid petrolatum. The effectiveness of the drug has been explained by its colchicine-like action on the cell nuclei. All forms of therapy whether chemical, thermal or surgical are directed at destruction. Gersh urged surgical removal of the lesions accompanied by circumcision in order to eliminate the possible development of the giant lesions.[4,5] When the lesions are large and are destructive, partial or complete penile amputation becomes necessary.

It appears to be Gersh's conviction that the presence of a prepuce and the accompanying moisture beneath it, predisposes to the development as well as the recurrence of condylomata acuminata. For that reason he believes circumcision would prevent recurrence or the development of giant destructive condylomata. In reviewing his results of therapy with podophyllin in tincture of benzoin, Barrett reported twenty-eight patients who were retreated with recurrent verrucae from one to three times before complete clearing occurred. These patients were not circumcised. Thirteen other patients were treated with 20 per cent podophyllin in tincture of benzoin, followed by circumcision. There were no recurrences in this group.

The following cases are presented to illustrate further the questions concerning the proper approach from the standpoint of therapy and accurate diagnosis. The cases also demonstrate that the destruction may progress over a long period of time with tissue loss but without a threat to the individual's life expectancy.

Case Reports

Case 1.—E. D. B., a white man, aged fifty, first noted a small papule on the coronal sulcus in 1937. The papule grew, became painful and spread to the surrounding area on the glans penis. In 1938 he was circumcised and the warts were desiccated. Desiccation was carried out at irregular intervals from 1938 to 1942. At the time he enlisted in the Navy in October, 1942, the penis looked normal except for a small area of discoloration where warts had formerly been. Patient was discharged in October, 1945. A small asymptomatic lump had developed at that time. In 1946 new warts developed and a biopsy was taken at the University of Minnesota. Since then the patient had repeated desiccation of lesions followed with podophyllin tincture applications at irregular intervals. The patient complained of a great deal of pain from podophyllin and the desiccation. From 1946 to February, 1952, he received the treatment at intervals. With the year 1953 the lesion had again grown to larger proportions. A biopsy specimen was taken in July, 1953.

Report of biopsy tissue taken from glans penis: *Gross:* The specimen is a triangular piece of tissue 8 by 7 by 7 mm. and approximately 3 mm. in thickness. It appears to be necrotic and is mottled red and brown in color. *Microscopic:* There is hyperkeratosis and parakeratosis to a marked degree. There are numerous granular basophilic areas that appear to be calcium deposit. There is a thin band of lymphocytes present. There is a thickened squamous epithelium that has blunt sharply demarcated lower surface. There is some acanthosis of the adjacent epidermis. There is no evidence of malignancy present. *Diagnosis:* Benign condylomata of the glans penis.

The patient was admitted to the United States Veterans Hospital on July 9, 1953. His chief complaint was shortness of breath for six weeks. There was a past history of rheumatic fever in 1912 at age 10. He had been hospitalized for heart failure in February, 1952 and March, 1953. The verrucous lesion had grown and spread to the surrounding area on the head of the penis (Fig. 1). It was quite painful.

E. D. B. was readmitted for the last time on September 21, 1953. He was comatose at that time and expired on September 28, 1953. At the time of death there was a large cauliflower-like vegatative lesion involving the ventral surface of the glans penis and measured 3 by 3 by 1 cm. Autopsy examination revealed no evidence of carcinoma or metastases.

Case 2.—T. A., a forty-two-year-old white man, first consulted a physician on July 1, 1949, concerning a wart which appeared on the glans penis. Because of the possibility of cancer, the wart was excised widely. The pathological report on the excised material was that of chronic inflammatory tissue. Since that time the lesions had grown considerably. The patient had no other symptoms except some increasing fatigue and weakness during the past two months. The glans penis was markedly enlarged with a fungating growth which appeared localized in its greatert portion to the underside of the glans penis. The end of the penis was enlarged about three times normal size. There were no areas of frank ulceration. A great deal of secondary infection was present. An urethral fistula was present just behind the frenulum which appeared through the center of the fungating growth, on the ventral portion of the penis. A few shotty nodes were present bilaterally in the inguinal region but these were freely movable and none were larger than pea size.

On admission the clinical diagnosis of carcinoma of the penis was made. A punch biopsy was performed September 1, 1949, and reported as consistent with the diagnosis of chronic inflammation. Because there was some question of the type and source of this biopsy, on September 4, 1949, the patient was taken to surgery, and two sections were excised from the edge of the lesion near the glans penis. Both of these sections showed no carcinoma to be present and were consistent with a diagnosis of chronic inflammatory tissue and benign papilloma. At the time of surgery approximately 30 cc. of pus was aspirated from one abscess cavity on the ventral portion of the shaft of the penis and multiple fistulae were noted all through the glans. These cavities were opened and the fistulous tracts probed and drained (Fig. 2). Under treatment the swelling and edema of the glans gradually subsided. However, another area of the fluctuation developed near the glans. This was opened and drained within the next few days. Biopsy specimen of the lesion was obtained and reported.

Report of biopsy specimen from penis, August 4, 1949: This portion of tumor shows only the appearance of a benign papilloma. There is no definite evidence of malignancy from the sections. *Diagnosis:* Papilloma.

On August 16, 1949, multiple abscesses about the glans were treated and the superficial papillomas were fulgurated. He received a total of 3100 roentgens to the penis from August 12 to September 12, 1949. The lesions seem to regress somewhat under the irradiation therapy. On September 16, 1949, an external meatotomy was done. A new urinary fistula developed on the ventral lateral surface of the glans penis. On November 3, 1949, a redundant portion was excised down to the urethra ventrally. In December, 1949, following this he was given a course of bismuth subsalicylate with no appreciable effect in the course of the lesions.

Report of tissue removed from penis with biopsy punch, January 10, 1950: Examination of the portion reveals it to be covered by a stratified squamous epithelium which shows a marked acanthosis and a papillary irregularity of the outer surface. Examination of the epithelium reveals considerable dyskeratosis. No good evidence of invasion is seen but the dyskeratotis change in the epithelium suggests that this is possibly changing into a malignant process. This is not a convincing carcinoma but certainly represents a precancerous growth. *Diagnosis:* Papilloma of penis showing questionable malignant change.

Penis was amputated on February 2, 1950. Lesion healed well. The patient is living and well to date.

Discussion

Two cases of benign destructive giant condylomata have been presented. In one case a dorsal slit was performed during the course of treatment without any change in the progress of the lesion. The other case persisted and recurred over a period of sixteen years after the first surgical removal accompanied by circumcision. At one time there were only small pigmented scars and no warts. Recurrence developed nevertheless. It is the writer's opinion that persistence and recurrence of this type of wart is similar to that seen in other types of warts. Some patients have a peculiar susceptibility to warts and respond poorly to all forms of therapy. In other patients almost any form of therapy will be effective. These are the factors which confuse the evaluation of treatment results in patients with warts.

The giant (carcinoma-like) condyloma is a special and unusual lesion. Good hygiene, circumcision and early therapy will help prevent their development. However, individual patient susceptibility may play a role in the development of such a lesion.

PRESENT STATUS OF MULTIPLE SCLEROSIS

Forty of the world's leading research investigators in the field of multiple sclerosis met in the Conrad Hilton Hotel, Chicago, on June 12, for the Eighteenth Session of the Medical Advisory Board Meeting of the National Multiple Sclerosis Society.

International guests of the Medical Advisory Board were Dr. Douglas McAlpine of the Middlesex Hospital, London, England, and Dr. R. S. Allison of the Royal Victoria Hospital, Belfast, Ireland. They addressed the meeting, describing the multiple sclerosis problem in their respective countries.

Seventeen research applications for financial support from the National Multiple Sclerosis Society were reviewed; ten of these represented proposed projects, the remaining seven being applications from investigators already being sponsored by the Society.

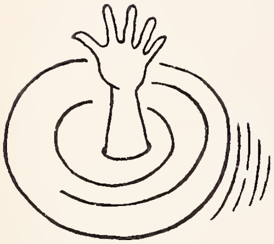
Fifteen currently sponsored investigations were discussed and analyzed by the medical board. Among them were the report of Dr. Harry M. Zimmerman, of the Montefiore Hospital, New York City, who has established a Central Pathology Registry in Multiple Sclerosis. The studies presently being conducted at the Mount Sinai Hospital in New York City under the direction of Dr. Harry Sobotka were also reviewed. They seek to learn what role, if any, vitamin substances play in the cerebrospinal fluid, and whether such changes, if they exist, can be related to a multiple sclerosis patient's problems.

Dr. Hans H. Reese, Professor of Neuropsychiatry, University of Wisconsin Medical School, and Chairman of the Medical Advisory Board, and Dr. Augustus S. Rose, Professor of Medicine in Neurology, University of California, Chairman-elect, presided. A summary report was delivered by Dr. Harold R. Wainerdi, Medical Director of the National Multiple Sclerosis Society.

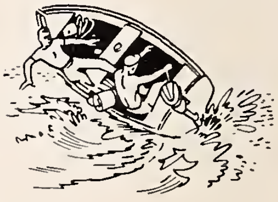
The Society has supported forty-eight research projects, including five research clinics, at a total cost of $792,414, during the nine years since its founding. During that time, an average of 41 per cent of all funds has been spent on research programs. The only national voluntary health agency dedicated to combating multiple sclerosis and allied neurological diseases through its programs of research, rehabilitation, patient service and clinics, the Society is presently seeking a minimum of $2,000,000 to meet these needs.

Water Safety for Minnesotans

JOHN R. HARTMANN
Minneapolis, Minnesota



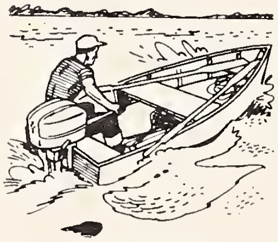
Of 6,700 drownings in the United States in 1954, there were 111 in Minnesota. In 1953, Minnesota numbered 156 drownings. Ninety million Americans use our swimming facilities throughout the United States. It has been conservatively estimated that the above number of people swim 2,000,000,000 times per year.



Avoid sharp, sudden turns at high speeds, and save yourself a ducking!

The Problem

If statistics are correct, 90 per cent of the millions who use our water facilities for recreation, or other means, swim very poorly or not at all; 10 per cent swim very well or reasonably well, and only a small percentage have the ability to assist others in need.



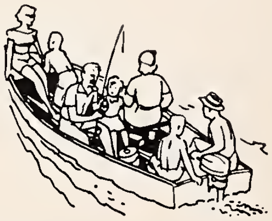
Overpowered boats are extremely tricky to handle. Match motor to boat.

Millions of people use the water as a means of transportation for business or pleasure. The majority of these people do not know the limitations of small crafts or have the ability to handle them safely. At one time, not too many people were in a position to purchase small craft, but today boats of all kinds are within easy reach of the average wage earner, and are operated by people at the risk of their own lives and the lives of others. Leading manufacturers stress safety in the construction of small craft.

Pre-season and post-season drownings have caused a large number of fatalities due to subnormal temperatures of the water. Very few swimmers can survive more than a very few minutes in subnormal water. With water safety education people need not die from drowning.

The Reason

People are handicapped in the water by habits they have acquired in their movements on land in an upright position. This position has been well established in a person's mind, and he will fight to assume it; therefore, little or no progress will be made if he is accidentally thrown in the water.



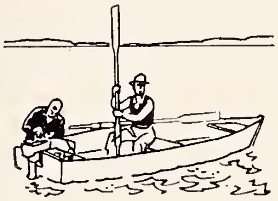
Overloaded boats swamp easily. Don't take the whole crowd at once—take turns!

There are a great number of people who believe that if one is thrown into water he instinctively swims for shore. Animals are born with this ability because movements are horizontal. People have to acquire this position under a competent instructor who teaches safety, how to avoid panic, ease of movements and how to conserve energy.

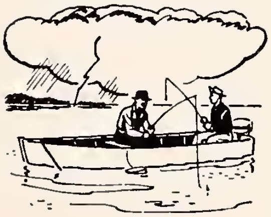
Mr. Hartmann is director of First Aid and Water Safety Services, Minneapolis and Hennepin County Chapter of The American National Red Cross.

Conditioning

To swim safely, for even a short distance, one must be in good condition and in order to have sufficient reserve stamina one must swim at least once or twice each week. Ninety per cent of the 90,000,000 people who swim are poor swimmers as they swim not more than seven or eight times a year and are therefore in poor condition. This also applies to other sports. Spur-of-the-moment sportsmen may find themselves in a desperate situation of exhaustion because of their poor physical condition. Regardless of all the warnings publicized by the press, radio, TV, posters and educational organizations, there are people who believe that a warning is not for them. Let's not fool ourselves—warnings are for *every one of us* if we want protection in and around water.



Stick with your boat in any kind of distress—motor failure or capsizing.



Head for shore the moment a storm comes up. Dawdling is risky.

Progress

Tremendous strides have been made since 1902 when the great Commodore Longfellow of the American National Red Cross pioneered the water safety program. One of his famous quotations was *"You can't think of a better sport to save your life."* Water fatalities have been reduced by 50 per cent through safety education. This was made possible by the work of leading organizations such as the YMCA, YWCA, Boy Scouts, schools, colleges, park boards, beaches, state recreational departments, American Red Cross and numerous other organizations that have not been mentioned. This reduction in fatalities would never have been made possible without all organizations co-operating. The American Red Cross alone issues 891,200 certificates in water safety annually, and has 42,000 authorized volunteer Water Safety Instructors throughout the United States.

ARTIFICIAL RESPIRATION

In the new back pressure—arm lift method, the victim is placed prone with the elbows bent and with one hand on the other. The cheek is placed on the hand, with the face turned slightly to one side. The operator kneels on one knee at the head of the victim. To start, the operator places his hands on the victim's back so that the thumbs just touch and the heels of the hands are just below a line running between the armpits.

He then rocks forward slowly, keeping the elbows straight, until his arms are approximately vertical, exerting steady pressure upon the chest.

Then he rocks backward, slowly sliding his hands to the victim's arms just above the elbows. Continuing to rock backward, he raises the arms until resistance and tension are felt at the victim's shoulder. Then he drops the arms and thus completes a full cycle. The cycles are repeated twelve times a minute, the expansion and compression phases being of equal length, and the release periods of minimum duration.

Caution: Never administer this method to a young child or an expectant mother. Artificial respiration is taught in Red Cross first-aid classes. It is important to give it properly. The best way to learn how to do it correctly is to take a course from a volunteer Red Cross first-aid instructor.

SAFETY SWIMMING RULES

1. Don't swim alone.
2. Wait an hour after meals before swimming.
3. Don't swim if tired or overheated.
4. Swim close to shore.
5. Don't ignore muscle cramps. Leave water immediately.
6. Don't swim from boats in deep water.
7. Be wary of river currents.
8. If your boat capsizes, stay with it.
9. Never stand or change positions in boats.
10. Don't overload boats.
11. Select a safe swimming place, preferably lifeguard-manned.
12. DON'T TAKE CHANCES AND—know how to save a person from drowning and how to apply artificial respiration by completing a Red Cross lifesaving course.

Common sense, you say? Yes, but three out of four drownings occur within 60 feet of shore—a stone's throw from safety.

Laboratory Aids

THE DIAGNOSIS OF PANCREATITIS BY LABORATORY METHODS

SAMUEL T. NERENBERG, M.D., Ph.D.
Minneapolis, Minnesota

A correct diagnosis of pancreatitis depends on the attending physician's being suspicious that the condition is present and the use of laboratory tests to substantiate such a diagnosis.

The diagnosis of pancreatitis is often missed because the condition is not considered in the differential diagnosis. It has been aptly recommended that a determination of serum amylase should be done routinely on the admission of any patient with acute abdominal disease, just as routine leukocyte counts are done.[1]

Pancreatitis is classified most simply by dividing it into two main categories, namely (1) acute pancreatitis and (2) chronic pancreatitis.

Acute Pancreatitis

The most important diagnostic laboratory test in this condition is a determination of the value for serum amylase done as quickly as possible in the course of the disease.[2] Serum amylase becomes increased shortly after the beginning of the clinical condition and remains increased for twenty-four to forty-eight hours. It may remain increased for a longer period but often it does not. If this test is done routinely on admission of all patients suffering from acute abdominal conditions, the diagnosis would be established in the great majority of patients who subsequently prove to be diagnostic problems. It must be emphasized, however, that not all patients who have acute pancreatitis will show an increase in serum amylase. When the disease is most severe and extensive destruction of the pancreas is present, the necrotic tissue secretes little or no enzyme, and as a result the blood levels are not increased. It has not been shown, however, that patients with such severe lesions do not routinely have increased serum amylase early in the course of the disease.

Other laboratory tests are available in the diagnosis of acute pancreatitis, the principal one of which is the determination of the level of lipase in serum and urine. Some authors consider that this test is helpful later in the course of the disease, when levels of serum amylase have become normal. This procedure is used by relatively few laboratories.[3,4] The results are not available for twenty-four hours because of the prolonged incubation period that is necessary. This delay is critical when one is trying to decide on the necessity of an emergency laparotomy.

Collateral laboratory evidence of acute pancreatitis consists of a decrease in blood calcium, which usually does not occur for three to four days after the attack, and transient hyperglycemia (not glycosuria) which occurs in 5 to 10 per cent of cases. Neither of the latter two tests is of great diagnostic value because the changes occur in relatively few cases of acute pancreatitis. When the blood calcium decreases to less than 7 mg. per 100 ml. in pancreatitis, the patient has a poor prognosis for recovery. Other tests, such as the antithrombin titer,[5] have been described but these have not been established as yet as reliable procedures.

It is apparent, therefore, that the laboratory diagnosis of acute pancreatitis relies almost completely on the demonstration of increased values for serum amylase very early in the disease. It must be remembered that an increase in serum amylase may occur in nonpancreatic conditions, such as perforated peptic ulcer, peritonitis, intestinal obstruction and dissecting aneurysm; the use of opiates also may lead to such increases.

This is the twenty-eighth in a series of editorial reports sponsored by the Minnesota Society of Clinical Pathologists and designed to foster closer relationships between clinicians and pathologists.

Dr. Nerenberg is pathologist, Asbury Hospital, Minneapolis.

However, the values under such conditions almost always are less than 300 Somogyi units.

Chronic Pancreatitis

Under this heading are included instances in which the disease is of a prolonged nature, in the form of either recurrent attacks or persistent damage following an initial acute attack. Determinations of serum amylase are of much less value in the chronic form than in acute pancreatitis. Increased values commonly are found during the acute phases of recurrent attacks. Obviously, in those cases in which extensive destruction of pancreatic tissue has occurred, insufficient tissue remains to form amylase, which is reflected by normal values for this enzyme. Faulty metabolism of carbohydrate, protein and fat is present as the result of extensive destruction of pancreatic tissue. It is in these cases, therefore, that examination of the stool for an increase in total fat, undigested fat and fatty acids is helpful. Increased values are not diagnostic in themselves, since similar findings occur with overactive peristalsis when the transit time through the intestine is decreased.

The secretin test of pancreatic function[6] has been advocated in the diagnosis of chronic pancreatitis. In this test, following a twelve-hour fast, the duodenum is intubated and a dose of 1 unit of secretin per kilogram of body weight is given intravenously. The duodenal contents are collected at twenty-minute intervals for eighty minutes. A reduction of the volume of pancreatic secretion with maintenance of bicarbonate and enzymatic secretion is said to favor tumor, while secretion of normal volumes with a diminished bicarbonate response is said to favor chronic inflammation or fibrocystic disease.[4]

Summary

The laboratory is of great help in the diagnosis of pancreatitis, especially in the milder forms of this disease. It has been increasingly apparent that the disease is much commoner than heretofore suspected. However, as in most other diseases, results of laboratory tests cannot be relied on as a substitute for good clinical judgment. Increased values for serum amylase are extremely helpful as an aid to diagnosis in pancreatitis, but the values are not always increased, especially in extremely severe disease when laboratory help is most needed. Furthermore, the time during which the laboratory can be of greatest aid in cases of acute pancreatitis is limited to the first twenty-four to seventy-two hours of the attack. The laboratory is of less help in the diagnosis of chronic forms of pancreatitis. In the latter condition, clinical judgment, roentgenologic examination and laboratory tests all contribute a share to the diagnosis.

Current Concepts

IATROGENIC HEART DISEASE

CHARLES N. HENSEL, M.D.
Saint Paul, Minnesota

Typical Case History

Mrs. M. M., aged sixty, married, a social worker, stated on her first visit, May 8, 1945, "I have a heart condition and I want to know what that condition is."

She said that her heart skips beats, but mostly when she is in bed at night. She stated that some months ago, she was awakened from sleep about 5 a.m. with a severe pain in her left chest, located half way between the nipple and the breast bone, that she broke out in a clammy sweat and expected death at any moment.

The doctor arrived in a short time and gave her amyl-nitrite to inhale and the chest pain which already had begun to lessen, completely disappeared.

Later that day she was taken to the hospital, where her sedimentation rate was reported as 6 mm. and her electrocardiogram as "not diagnostic"; however, she was kept in bed, in the hospital, for thirty-three days.

While there, her blood pressure, which was recorded as 184/94 four months before the attack, was reported as 146/84. She was told that the second electrocardiogram showed very little change; however, she was warned that she had a serious heart condition and was advised to be careful.

She stated that since leaving the hospital she has worked short hours and done no house work.

Heart Symptoms.—She stated that she had an occasional "flick" of pain in the left chest in the daytime, but that at night, when she gets into bed, she is conscious of her heart working slowly and hard and that after a few minutes she trembles all over and even her teeth chatter. Then she gets warm all over.

Such spells may come every night for three to four weeks and then be absent for several nights. She stated that during the daytime, she is not conscious of her heart. She had raised four children and had always been healthy.

The physical examination revealed a ruddy cheeked, healthy appearing woman with a slightly enlarged thyroid gland containing several nodules, some hard and some elastic. The throat showed no abnormalities. The lungs were clear.

The heart was not enlarged, the action was brisk and forceful, the rate was 80 beats per minute and the rhythm was regular. The blood pressure was 176/96.

The abdomen was normal. The knee jerks were present and equal. There was no edema.

X-rays showed a normal heart, the electrocardiogram was normal, the blood count and blood chemistry and urine were all normal.

The basal metabolism was a minus 6 per cent and pulse rate during the test was 60-58-56 beats per minute.

She was told that her heart was normal and that there was no evidence of coronary disease, but that quite obviously, she had been badly frightened by the belief that she had serious heart disease and that fearful thoughts could make her heart misbehave.

She was told that since she did not have heart disease, she needed no medicines and needed no restrictions on her activities and should go home and lead a normal life.

A week later she reported that she was now sleeping well at night, that she no longer had chest pain and was not bothered when getting into bed at night. Her blood pressure was 124/80 and her heart rate was 72 beats per minute and regular.

Three years later, she reported that there had been a number of sudden deaths in her town and she had again become concerned about her heart. She was belching, there was gas rumbling through her bowels, and she felt occasional pain in the left chest.

On examination, recumbent, her blood pressure was 190/100, ten minutes later 176/90 and after a further rest 156/80. Her heart action was strong and regular. X-rays and an electrocardiogram again gave normal findings.

Nine years after her first visit, March 11, 1954, she reports that she has been living a busv and an active life, and that she nursed her husband through a "stroke" five years ago.

As to her heart, she told me that occasionally. at night, if she thinks too much, she gets an inner trembling and at such times she can feel her heart beating against her ribs, but that this no longer frightens her. She stated that she is not conscious of her heart in the daytime when she is busy.

MANAGEMENT OF THE FEDERAL DEBT

The objective of monetary policy, as determined by the Federal Reserve System, of fiscal policy, as determined by the legislative branch of the government, and of debt management, as determined by the Treasury Department, is economic stability through the maintenance of high employment, rising production and steady prices. The Research and Policy Committee of the Committee for Economic Development has recently released an interesting and thought provoking statement on *Managing the Federal Debt.*

The importance of debt management and its impact upon the economy has come sharply into focus since the war. In 1929, the Federal debt constituted only 8 per cent of all outstanding public and private debt, while today the Federal debt accounts for approximately 36 per cent of the total debt. The Federal debt held by the public at the end of 1953, excluding that part owned by the Federal Reserve Banks and various Federal Government accounts, aggregated $226.9 billion. The importance of the Federal debt upon the economy should not be measured in absolute size, but rather as a ratio of the size of the debt to the size of the national income. Since the end of the war this ratio has declined from 127 per cent to 74 per cent; the greater part of this decline having resulted from the increase in national income.

In deciding what is the "proper composition" of the Federal debt at any given time in order to minimize the effects of inflation and deflation upon the economy, five factors must be taken into consideration:

1. Too large a proportion of short-term debt requires frequent borrowing by the Treasury and may handicap the Federal Reserve in curbing inflationary tendencies.

2. On the other hand, too small a proportion of short-term Federal debt may tend to accentuate deflationary tendencies by restricting bank lending and private spending.

3. If the Treasury were to shift from short-term to long-term debt, some private businesses might be induced to shift to short-term borrowing. Such a shift in substantial proportions would make business more vulnerable to a recession.

4. Changing economic conditions are reflected in substantial fluctuations in the market value of outstanding long-term Federal securities. Such fluctuations in market prices tend to have a stabilizing influence upon the economy.

5. A wide distribution of the Federal debt among maturities and holders is an effective method of transmitting credit ease or tightness to other segments of the capital market.

In order to attain a greater degree of economic stability, the CED recommends that the debt structure be modified in four respects:

1. "The amount of very short-term marketable debt, due within one or two years, should be smaller."

2. "Most of the increase to take the place of the reduced volume of short-term marketable debt should be in the marketable debt of intermediate term, say up to ten years."

3. "The long-term marketable debt oustanding should be moderately larger."

4. "A larger part of the total debt should be in the form of savings bonds."

Edward B. Chapin
Assistant Vice President
First National Bank of Saint Paul

THE DIABETIC PATIENT AND HIS CHEST X-RAY

It is recognized that patients with uncontrolled diabetes mellitus are predisposed to certain diseases. X-ray examination of the chest may be of assistance in finding some of these conditions. In this category belong pulmonary tuberculosis, lung cancer, lung abscess and pulmonary congestion. Roentgenograms of the chest are preferable to fluoroscopic examination. In any event, more time should be spent with the inspection of the right lung than of the left lung. Normally, from 53 to 56 per cent of the air inhaled goes to the right lung. Consequently, proportionately greater number of pathogenic microorganisms and larger amounts of carcinogens are deposited in the right lung than in the left lung. Primary tuberculosis, primary bronchogenic cancer and lung abscess are found with a correspondingly higher frequency on the right side. Patients with diabetes mellitus should have a roentgenogram of the chest every six months.

The highest incidence of pulmonary tuberculosis is observed in young adult men. Both in primary and in reinfection forms of this disease predominantly exudative lesions are common. Concurrent enlargement of the hilar lymph nodes is frequent in primary tuberculosis. One should look for configurations suggestive of cavity. Also, one may see a radial linear shadow connecting the hilus to the disease focus. It represents lymphangitis. Bronchopneumonia or lobar pneumonia of tuberculous origin may be noted. It is well to keep in mind, however, that in a great many instances the tuberculous process appears as a localized conglomeration of small nodules. Rarely, one may find a round, "coin," shadow of 1 to 3 cm. in diameter. When such circular shadows are multiple, they are suggestive of metastatic tumors. Miliary nodules or larger, coarse nodules widely scattered in both lung fields are also encountered. The apex of the lung may be free of disease. Predilectional site for early reinfection type of tuberculosis is the superior retroradicular region. Early pleural tuberculosis is uncommon. Occasionally, fibrinous pleurisy or tuberculous pleurisy with effusion may complicate specific lung involvement.

The increased incidence of primary bronchogenic carcinoma in patients with diabetes is attributable to the following causes.

1. The tissues of these patients are older than their chronologic age. For reasons unknown, senescence is the period when epithelial cells become anarchistic and develop a tendency to uncontrollable proliferation and spread.

2. Cancer cells are "glycophilic." They thrive on dextrose. This has been demonstrated in tissue cultures. Obviously, hyperglycemia represents a favorable environment for cancer growth.

3. Hepatic dysfunction in uncontrolled diabetes results in hypovitaminosis A. It is known that lack of vitamin A causes hyperkeratotic metaplasia of the bronchial mucosa. Such changes may be looked upon as the premonitory phase of lung cancer.

The high incidence of lung abscess is explained on the basis of immunologic inferiority (cellular and humoral) of the body. Also, aspiration of infected material from the oropharynx and mouth during coma is instrumental in the causation of lung abscess.

Heart failure resulting from vascular degenerative changes may lead to pulmonary congestion and edema.

In closing, it is well to emphasize a few pertinent points.

1. Roentgenogram of the lung is only one of the sources of diagnostic information. X-ray pictures represent shadows which do not reveal the nature of the disease casting the shadow.

2. X-ray shadows must be interpreted in the light of other diagnostic data and findings which are procured by history-taking, physical and laboratory examinations.

3. It does not detract an iota from the dignity of the medical profession to admit to the limitations of x-ray examination. On the contrary, cognizance of these limitations adds to the profession's intellectual integrity and to the doctor's diagnostic competence.

Andrew L. Banyai, M.D.

HAROFE HAIVRI

We recently received a copy of *Harofé Haivri.* It evoked thoughts, memories, and sensations—all pleasant—which we shall discuss in part and circumstantially (if we were poetic, this could be classed as imaginative rather than circumstantial).

First of all, we owe Dr. Moses Einhorn, the editor of the bilingual *Hebrew Medical Journal (Harofé Haivri),* our thanks.

Next, we are reminded by the Hebrew letters and the pagination from back to front, of Dr. Matas. *That* reminiscence goes like this: A friend of ours interned in New Orleans about twenty-five years ago specifically to be able to work under Dr. Matas. Even then, Dr. Matas was a venerable old man of medicine. In the course of making rounds one day, the staff trooped into the private room of a little, old Hebrew lady. The only means of communication between her and Dr. Matas was Hebrew, with which the linguistically accomplished doctor struggled somewhat haltingly. Finally the staff filed out of the room again and Dr. Matas, already past the age at which most men retire from work, and surely from any pretense of learning anything new, said, with only a minor note of irritation, "Well, well, now I'll have to brush up on my Hebrew." We don't have any Hebrew to brush up on, so we are still trying to figure out how come this journal was sent to us. The accompanying letter gave us no sales talk; it didn't even mention a subscription price, as a matter of fact.

A classmate of ours used to point out that we should be smart enough to call on his medical fraternity if our class needed any of its financial affairs managed. We are also convinced that we might well call on the same Hebrew fraternity's scholars for well-written medical papers. We base this judgment on English papers in this issue of the *Hebrew Medical Journal,* as well as on articles from other journals.

We enjoyed particularly the series of short articles on Maimonides, written in honor of his 750th anniversary. And the section on Medicine and Religion consists of an article by an Irishman, I. Jakobovits (this copy of the journal arrived on St. Patrick's Day, and, lest you misapprehend, we point out that this Irishman is not only from Ireland, but is the Chief Rabbi of Ireland) entitled *Sterilisation and Eugenics in Jewish Law* that is a readable, scholarly discussion of this moral-socio-economic topic.

Because at least some of you will have a sufficiently inquiring mind to want to pursue these reveries to their source, we tell you that Dr. Moses Einhorn's address is listed as: 983 Park Ave., New York 28, N. Y.

H.G.M.

FLEXIBLE FARM PRICES

Under our heritage of American competitive enterprise systems, the prices paid to farmers for the products they produce should be consistent with the consumptive demand for that product. The voters in the market place have helped for years to determine generally what farm prices should be and what the farmers should produce. Farm prices should have a relatively free interplay of the market in response to demand and supply level.

In 1938, the Congress of the United States passed the Commodity Credit Loan Act which has been highly abused as far as its original purpose is concerned. In the later depression years, the farmers that were left were in rather tough financial shape and the Commodity Credit Loan program was simply a government guaranteed loan program which would enable the farmer to hold his produce until the market could firm up and he could get a better price. In this way, the farmer would get his money from the market place—not government. The government only acted as a loan guaranteer to the banks or elevators that were actually loaning the money.

The same act established the "old parity formulas" which was a simple mathematical calculation of what a unit of a farm product was worth. This "true value" or "100 per cent of parity" value of each crop bushel was calculated from farmers' costs. As farmers' cost rises, the parity or "true value" calculated price should also rise proportionately. The same act provided that these loans to farmers should be set up on a graduated or "flexible" scale basis.

The annual loan guarantee was to be set on each basic farm product each year commensurate with the *supply needs.* If the supply produced was larger than the combined total of (1) domestic need, (2) export need and (3) normal reserve as provided for by law then we would have a "surplus" and supports should drop on a "flexible" scale of one (1) point support drop for each 2 per cent additional surplus produced and not sold. This was to increase sales, discourage production of that commodity and keep the government from having to buy and store and compete for a later market against the farmer.

In 1938, the support level ranged from 75 to 52 per cent of parity depending on supply. Congress later amended the act to provide for price supports on basic crops at 90 per cent of parity or "true value" for the duration of the war and two years after in order to stabilize farm income.

In some crops, wheat as an example, the "support level price" was high enough to be a profitable price and as a result, we have now over a two years supply of wheat on hand, mainly in the hands of the government competing for current markets. At the same time the farmers are under government enforced acreage cuts, less than "true value" prices and are really getting hurt.

This is a perfect example of government bungling of a private enterprise business.

The politicians bought farm votes with "high rigid price supports" and in turn they took away the farmer's market, his right to fully produce and his opportunity for management decision.

Farm Bureau, the voice of agriculture, along with the help of others including independent and professional businessmen is determined to break the ever tightening band of government controls and "political paternalism" that can only lead to the downfall of our free enterprise system.

J. Delbert Wells
Secretary, Minnesota Farm Bureau Federation

GENERAL PRACTICE RESIDENCY

There has been a growing trend recently for hospitals to provide residencies designed for general practice. This type of residency has long been needed to fill a need for the development of further training to the men who desire to specialize in general practice. Men who select such residencies do so in order to round out their previous medical training. This program provides them with an opportunity to learn the nature of general practice. It further enables them to come in contact with men who are engaged in family practice and to learn from them the art, as well as the science, of medicine. A well-developed general practice residency gives the participant an opportunity to see and assist in the practice of medicine on the community level. It also enables the participant to gain some insight as to the problems and the nature of such a practice.

The general practice resident has an opportunity to see the application of medicine to the individual as a whole, rather than the specialized approach to the patient in which an organ, or group of organs, is studied and treated. During this residency, however, the physician is trained not only by men who are engaged in general practice but he also is trained by specialists in the various fields of medicine. An association of the general practitioner with the specialists in this training program has proven to be of invaluable assistance to the student physician. This type of residency should be further developed, and more opportunities should be available for men who are to engage in general practice so that they may have these residencies available to them. The quality of such a residency, and the benefit that accrues to the physician who engages in such a residency is immeasurable and will reflect itself on the medical care he renders to the families in his community.

A. E. Ritt, M.D.

DROWNINGS—A KILLER OF MINNESOTANS

With summer upon us, the problem of drowning in one of our ten thousand lakes (to say nothing of our many rivers, brooks, sloughs, wells and cisterns) is with us for several months ahead. Have you given your safety vaccination shots for water hazards? Have you spoken to your young mothers about children's supervision at the beach, life preservers when in boats, swimming safety rules?

Drowning is one of the leading "killers" of Minnesotans! Do peruse Mr. Hartman's comments in this issue on "Water Safety for Minnesotans."

Tague C. Chisholm, M.D.

THE SCIENCE REPORTER

With Americans demanding more and more information about all types of scientific developments and medical progress, the role of the science reporter gains in importance daily.

It's time to face it—the science writer is a permanent fixture on American newspapers.

But as he gains in importance, he also must assume greater responsibilities, not only to his readers but also to the medical man, the physicist or the biochemist with whom he deals.

The wariness with which both the scientist and the science reporter often regard each other must be supplanted with an atmosphere of trust and cooperation before both can fulfill their joint obligations to an information-eager public.

Problems voiced last summer, for example, during a panel discussion at the University of Michigan must be solved, and that can be done only through joint efforts on the part of both journalists and men of science.

Dr. Allen V. Astin, director of the Bureau of Standards, criticized the press for generalization, extending the bounds of a scientist's work —bounds that are carefully set.

On the other hand, Paul Block, Jr., publisher of the *Toledo Blade*, criticized scientists for an unwillingness to interpret the effects or the impact of their work and leaving that job to the reporter.

Both agreed that the scientist and the newsman have similar goals: to collect the facts and report them accurately. The big difference lies in the emphasis each places on those goals.

The scientist often is as much interested in the methods used to arrive at a specific goal as he is in the results themselves.

The reporter, by the very nature of his work, is primarily interested in the results of the scientist's labors and uses only those facts concerning methods that he feels are necessary to explain the procedures to his readers.

But it is not necessary to recount the arguments pro and con here. Suffice to say that only by learning more about the other's problems can we hope to eliminate any causes of friction that may exist between the two groups.

Who is the science reporter? What are his qualifications, his background?

Since few newspapers have an editorial budget large enough to include a full-time science writer—one who does nothing but feel the medical or scientific pulse of his community daily—most science reporters at present are of the "part-time" variety.

Today, they may interview a surgeon about a new operative technique. Tomorrow, or perhaps only an hour later, they may be covering a three-alarm fire.

Some men handling science news do so because their "beats" bring them into contact with researchers. The reporter covering the campus of a large college or university is an excellent example.

The average science reporter may or may not have had any formal education in the advanced sciences but he generally is a college graduate and has to be a competent newsman in order to hold down the job for any length of time. If he isn't competent, his scientific news sources dry up and he is no longer of any use to his paper.

He can get involved in science reporting any number of ways. He may have volunteered for the job primarily because of intense interest and as a result, what he may lack in educational resources he makes up for in enthusiasm.

Of course this educational lack or unfamiliarity with terminology can hinder him in relations with some scientists. Often he is forced to ask questions that seem extremely basic to the medical man or researcher (better that than have him attempt to bluff his way through without completely understanding the material discussed). It must also be remembered that not even the most experienced science reporter is familiar with all fields of science.

A good science reporter (as any good general reporter) is accurate.

Here, too, arises the question whether a science reporter should have his articles checked by the "expert" before publication. Most good reporters, I believe, do recheck their material when it is of a highly technical or specialized nature. The reporter is not any happier with major errors than is the source of his story. Such checking, however, generally is limited to errors of fact and not to style or method of presentation. (Suggestions to change a writer's style are akin to a layman's suggesting to a surgeon that he change the type of incision he uses for appendectomies.)

The good science reporter can and will keep a confidence.

A recent complaint registered by a man on a science run was that scientists refuse to keep him informed of the progress of their projects.

"I have no intention of printing anything until they say the word," the reporter explained. "I just want to follow the thing along so that when the story is ready for publication I'll know the background and have some basic knowledge of the work."

A science reporter should not attempt to sensationalize news but, as one writer pointed out, "When a subject like the development of cortisone is involved, how can you avoid it?" In the same regard, the reporter should remember that not all medical or scientific developments have immediate practical application.

Many critics of the present crop of science reporters deplore the fact that there are not enough fully qualified men in the field.

To such critics must be put the question, "Whose responsibility is it to see that more qualified writers are developed? The newspapers? Journalism schools? The scientists?"

Actually, all three have a deep responsibility in this regard.

Journalism schools should be encouraged to train more men in medical and other scientific fields of reporting. At present there are few schools that have curriculums designed to fill that need.

Newspapers should be encouraged to make a place on their staffs, whenever possible, for a full time science writer since the man who is a

President's Letter

LEGISLATIVE REVIEW

The Minnesota Legislature of 1955 considered and acted upon many items which are of interest to the medical profession of the state. Below is a summary of some of the most important items and the action that was taken:

Senate File 1174—This would have limited the state's share of the cost of medical, hospital, nursing home, and dental care, including drugs and medicines, to $25.00 per month for all cases of recipients of old age assistance. The chairman of the Senate Committee on Public Welfare worked vigorously for the passage of the bill, notwithstanding the united opposition of the medical profession, the hospitals, druggists, county commissions, county welfare boards and others. The proposal was overwhelmingly defeated in the House of Representatives. The sharing of such costs presently are on a 50-50 basis between state and county. In the future, the sharing will be state, 45 per cent, and county, 55 per cent.

The Legislature continued for two years more the appropriation of $75,000 per year for nurse training scholarships. Maximum scholarship is $600 for one studying to be a registered nurse; a maximum of $300 for one studying to be a practical nurse. Basis for the award is need and ability.

The Legislature again refused to grant full medical and surgical privileges to osteopaths. The bill also would have added two osteopaths to the State Board of Medical Examiners. The bill was defeated in the Senate.

For a second time, the Legislature refused to create an examining and licensing board for psychiatric aides. The bill was supported by some of the psychiatric aides at the state hospitals. There is serious doubt as to the need for such legislation.

The Legislature increased the maximum compensation of the administrators of state hospitals to $12,250 per year, plus complete maintenance.

The Legislature appropriated $400,000 toward the construction and equipment of a medical, dental, biological library building at the University of Minnesota. The University was authorized to accept any further sum for such purpose that may be made available by the Congress of the United States. The original request of the University for such a building was $875,000.

The Legislature appropriated $65,000 for mental health research in the fiscal year 1956 and $85,000 for fiscal year 1957. Also, $75,000 for the mental health training program in fiscal 1956 and $98,600 in fiscal 1957, of which $30,000 per year may be used for the employment of additional psychiatrists.

The Legislature again refused to authorize the corporate practice of medicine by consumer controlled groups and cooperatives. The bills did not provide for free choice of physician nor did they require any financial guaranty of the organizers.

On and after January 1. 1963, the requirement of high school education as a prerequisite to taking the Minnesota Basic Science examination is increased to one year of approved college education; after January 1, 1965, the requirement will be two years of approved college. The change will affect some chiropractic applicants.

It can be seen by the above that the Legislature this year considered a great many important measures which affect the medical and allied professions in this state, and that this large volume of legislation on medical and allied matters shows the increasing interest our legislators have in scientific and medical economic proposals.

AMA OFFICIALS HEAR POLIO REPORT

When the safety and effectiveness of the Salk polio vaccine were announced on April 12, a simultaneous scientific meeting was begun. Attending the scientific session on behalf of the American Medical Association was Board of Trustees chairman, Dr. Dwight H. Murray; President-elect, Dr. Elmer Hess; Assistant Secretary, Ernest B. Howard; and *AMA Journal* editor, Austin Smith.

The American Medical Association *Secretary's Letter* reports:

> "When the National Foundation for Infantile Paralysis announced that the vaccine works and is 80 to 90 per cent effective in preventing paralytic polio, the biggest medical news story of the century unfolded amid the fanfare and drama typical of a Hollywood premiere. More than 300 press, radio, and television people were on hand to cover the event."

Reactions were varied to the dramatic announcement. Said Dr. Murray: "The American people can be assured that the thousands of practicing physicians in cities, towns, and hamlets will give their wholehearted co-operation to get the vaccination programs under way as effectively and safely as is humanly possible." He urged parents to have patience and not rush to doctors' offices immediately because probably most parents already have immunity to the disease. "Give children priority," he added.

However, although the Ann Arbor event was a glorious day for American medicine, many politicians moved in with some "corny" statements and sickening actions, noted in the Secretary's Letter.

The *Letter* quotes a *Chicago Tribune* editorial:

> "No sooner had the worth of the Salk vaccine been scientifically affirmed than the Oregon maverick (Senator Morse) tried to get into the act. He introduced a bill in the senate for a five-man bureaucratic commission to take control of the vaccine out of the hands of the people who discoverd it and are supplying it, out of the hands of the medical profession which will administer it, and supply it to the nation as a blessing of the government."

The *Tribune* editorial goes on:

> "Government had nothing to do with discovering the vaccine. . . . You could lock Jaybird up in a laboratory, give him all the apparatus and materials needed, plus the most minute instructions from the discoverer, and he couldn't turn out a single usable portion of the vaccine between now and the time the voters of Oregon will have a chance to catch up with him. But now that the job has been done by others, he thinks he is just the man to take over. . . . Does he maintain that the physicians of the United States will be parties to extortion? Apparently he does, for this is Jaybird's song: 'You can't trust commercial interests. You can't trust doctors. If you want a polio shot, see your precinct captain.'"

Minnesota Program Outlined

Considerable confusion over the administration of the Salk polio vaccine in Minnesota has existed, as it has in most states. However, as of May 15, the situation was as follows:

The Council of the Minnesota State Medical Association approved the following priority schedule for vaccinations in private practice, to be administered after the first and second graders have been vaccinated under the program of the health department: (1) pregnant women, because they are most susceptible to poliomyelitis; (2) children in age groups fanning out from the six-to seven-year group, until all children from one through twelve have been vaccinated: five to eight, then four to nine, then two to eleven and finally all from one to twelve.

The Council also went on record against any "first come-first served policy" in the doctor's office. Also, until the supply is increased, the Council decided that the vaccine should be withheld from babies under one year of age.

The Minnesota Department of Health has issued several summaries of recommendations on the actual administration of the vaccine, also. Plans were to vaccinate all pupils of the first and second grades, using vaccine furnished by the National Foundation for Infantile Paralysis, thus covering some 133,000 children in the state. However, since the recalling of certain supplies of the vaccine by the federal government, the entire program has been held up pending final approval of batches already received, and approval of future batches to be received for the program. This approval, or a statement on the entire program as recommended by the federal government, was not yet available at the above-mentioned date.

CHARGES MADE AGAINST MORE HEALTH INSURANCE FIRMS

Five additional insurance companies were charged by the Federal Trade Commission with misrepresenting the benefits of the health and accident policies. The new charges bring to twenty-eight the number of companies against which the FTC has filed complaints. Two have agreed not to engage in the challenged advertising practices.

According to a recent story in the *Washington Post and Times-Herald,* "The five firms collect premiums of 35 million dollars a year in the billion-dollar field of individual policies on health, accident and hospitalization. All five were charged with misrepresenting in advertising the extent and length of coverage."

The new firms charged were: Educators Mutual Insurance Co. of Lancaster, Pa.; Beneficial Standard Life Insurance Co. of Los Angeles; Fireman's Fund Indemnity Co. of San Francisco; National Casualty Co. of Detroit, and Federal Life and Casualty Co. of Battle Creek, Michigan.

FTC Authority Upheld

Along this same line, a hearing examiner has ruled that the Federal Trade Commission has authority to police the interstate advertising of health and accident insurance companies. The ruling came as a result of two previously charged companies challenging the commission's jurisdiction over such advertising. Both of these companies asked dismissal of the FTC complaints on the grounds that the companies were adequately supervised by the states that licensed them.

However, according to a *New York Times* story recently: "Hearing Examiner Loren H. Laughlin held that Congress 'clearly intended' for the F.T.C. to police the interstate mail-order business of the companies. The two companies can appeal, if they choose to do so, and get a ruling from the commission itself."

INSURANCE COMPANY OFFERS CANCER RIDER

The Continental Casualty company now has on the market and for the first time cancer benefits up to $5,000 by rider to the accident and health group insurance plans covering 100 or more employes and to be sold through the company's general group division in all states except Maryland. According to the monthly house organ of the company, another new rider to group policies embraces ten dread diseases. These benefits, up to $5,000, may be sold with any basic general group plan.

According to the publication, "The cancer rider will cover for the disease when cancer is first diagnosed while the insurance is in force. Expenses taken care of will be those incurred within two years of the first treatment, beginning with diagnosis. They are payable in lieu of benefits that would otherwise be paid under the base plan. Employes' monthly premium for the cancer benefits will be 55 cents. The family rate for employe and eligible dependents will be $1.17 per month. It is emphasized that at the present time the benefits are available only to groups of 100 or more employes. They include hospital room and board, necessary services; physicians', surgical and nurses' fees."

The company also reports that the dread diseases covered for $5,000 aggregate include polio, scarlet fever, diphtheria, spinal meningitis, encephalitis, rabies, tetanus, tularemia, typhoid or leukemia, symptoms of which first appear while the insurance is in force.

GROUP CLINIC REGULATION UPHELD

A 1953 act of the California legislature regulating private out-patient clinics operated by groups of physicians was declared to be constitutional recently. An article in the San Francisco *Chronicle* noted that Attorney General Edmund G. Brown made the ruling, which was requested by Dr. Malcolm Merrill, director of the California State Department of Public Health.

The chief effect of the act is to prevent formation of medical groups under names that do not reveal the names of the physicians involved, as in the Permanente Medical Group, the Palo Alto Clinic and San Mateo Clinic, members of Brown's staff said. According to the news story: "Groups formed after January 1, 1954, are required to use the last name of at least one of the physicians involved, followed by the words 'Medical Group.'"

Success Undermined?

Apparently, some of the clinics and groups involved feel that the regulating law undermines their success. The story goes on to say: "Although the law does not affect actual operation of the groups, it was pointed out that some clinics believe a large part of their success is based on public familiarity with the established names. The law provides that any clinic established before 1954 can continue to operate under the established name unless there is a change in the partnership, in which case a new license must be acquired and the new regulation followed.

The article quotes Mr. Harry Fledderman, attorney for the sixty-member Permanente Health Group, who said:

> "It would be considered a serious matter if the group has to change its name. The Permanente partnership contracts to provide medical care in Kaiser Foundation Hospitals and also operates several out-patient clinics separated from the hospitals. The group sometimes takes in or loses several members of the partnership yearly, which may force a name change."

The article further states:

> "The law provides exemptions for out-patient clinics operated as integral parts of hospitals. The Legislature, when it passed the law, apparently felt that operation of clinics without including at least one name of a physician involved bordered on practicing under a fictitious name, members of Brown's staff said. There are 195 out-patient clinics in California that will be affected. Charity, teaching and research and employer clinics are exempt from the regulation."

THE MINNESOTA STATE BOARD OF MEDICAL EXAMINERS

230 Lowry Medical Arts Building
Saint Paul 2, Minnesota

F. H. Magney, M.D., Secretary

LICENSE OF MINNESOTA PHYSICIAN SUSPENDED FOR FIVE YEARS

In the Matter of the Revocation of the License of Kenneth L. Kelsey, M.D.

The Minnesota State Board of Medical Examiners on May 6, 1955, suspended for a period of five years the medical license held by Dr. Kenneth L. Kelsey, an Aurora, Missouri, physician who intended to open an office for the practice of medicine at Annandale, Minnesota. When Dr. Kelsey came to Minnesota in September, 1954, and attempted to pay up the arrears in his registration fees in reference to his Minnesota medical license, an investigation disclosed that he was personally using large amounts of barbiturate drugs, especially nembutal. A citation for the revocation of Dr. Kelsey's license was issued in which he was charged with habitual indulgence in the use of barbiturate drugs, and also with furnishing, prescribing and administering narcotic drugs to his wife, not in the bona fide practice of medicine.

At the time Dr. Kelsey appeared before the Board on February 4, 1955, in response to the citation, both he and Mrs. Kelsey had been hospitalized since the first part of October, 1954. Dr. Kelsey admitted the truth of the charges contained in the citation and, after he gave his promise to the Medical Board that he would refrain from applying for a narcotic tax stamp, the Board took Dr. Kelsey's case under consideration, the decision to be held in abeyance until it could be determined what could be worked out that would be beneficial to Dr. Kelsey and his wife. However, when Dr. Kelsey's case was again taken up by the Medical Board on May 6, 1955, it appeared that Dr. Kelsey had left the hospital on his own request in the latter part of February and had subsequently gone back to Missouri.

Dr. Kelsey was born in Saint Paul, Minnesota, on February 25, 1911. He graduated from the University of Minnesota with an M.D. degree in 1934 and was licensed to practice medicine in Minnesota in the same year. Before coming to Minnesota in the fall of 1954, Dr. Kelsey had practiced medicine at Aurora, Missouri, since 1936.

THE SCIENCE REPORTER

(Continued from Page 437)

part-timer is admittedly less qualified to develop science news adequately.

But a great deal of the responsibility also falls on the shoulders of the scientists, themselves. They should be willing to support any programs designed to get information about scientific progress to the public with speed, completeness, and accuracy.

The attitude that any medical man or researcher who is mentioned in the press is automatically a "publicity hound" or a violator of professional ethics hinders any such programs.

The problems that face the science reporter and the scientist in getting news to the public are vast and will not be solved quickly. But they will never be resolved until all interested parties are willing to lend a hand.

John R. Finnegan
Saint Paul Pioneer Press and Dispatch

The Dean's Page

THE FAMILY PHYSICIAN

In a recent issue of *The Chronicle* of Plymouth Congregational Church, Minneapolis, of which Mrs. Diehl and I are members, our minister, Dr. Howard J. Conn, published such a splendid statement of the spirit and service rendered by the family physician that I requested his permission to reprint it as follows:

> "I always think of Jesus as the family physician of the human race. Religion to Him existed for the purpose of action; it was valuable solely for the service of mankind."
>
> So wrote Sir Wilfred Grenfell, the great Labrador missionary doctor back in 1911.
>
> Think of the role of the family physician, and realize how strikingly Jesus Christ can play a similar part in our lives. The doctor seeks to
>
> —diagnose our ills;
> —appreciate the family background;
> —read the hidden thoughts of the patient;
> —understand the universal rules of health;
> —prescribe a course of action;
> —see the long-range possibilities as well as the immediate cure;
> —encourage us to co-operate;
> —love us in every situation;
> —draw forth the best in us;
> —blend medical science, divine power and human faith into a healing channel.
>
> What the dedicated doctor seeks to do for his patient, Jesus can do for the moral and spiritual well-being of the whole human race.
>
> But just as the doctor must be called before he can assist, so Christ must be welcomed into the heart. Lent is a period when we especially do this.
>
> God be praised for the family physician!
>
> God be praised for Jesus Christ, the family physician of the human race!
>
> God be praised when we invite Him in, and entrust our lives to His guidance!"

The Medical School of the University of Minnesota is striving to select and train young men and women to be "dedicated doctors" and "family physicians" of the type described by Dr. Conn. Incidentally, Dr. Conn is substituting for Dr. Ralph Sockman on the National Radio Pulpit—NBC— 9 a.m. Sunday mornings, C.S.T.

Public Health

PROGRAM FOR PROFESSIONAL PERSONNEL IN NATIONAL EMERGENCIES

The Commissioned Reserve of the Public Health Service is being expanded and reorganized for service in grave national emergencies as the result of a delegation by the Federal Civil Defense Administration to the Department of Health, Education and Welfare which was approved by the President on July 14, 1954. Commissioning of officers in the emergency reserve is under way.

Function.—There are three main groupings of professional personnel in the Commissioned Corps of the Public Health Service—Regular Corps officers, Reserve Corps officers on active duty and Reserve Corps officers in inactive status. It is the latter group that is being expanded and reorganized under the Service's emergency program.

Reserve Officers in inactive status, now and in the future, may apply for active duty and will be considered for available assignments. But no officer of the emergency reserve is subject to mandatory duty except in the event of a national emergency publicly recognized as requiring such action. Moreover, even in an emergency, an officer of the emergency reserve already performing important health duties would be assigned to active duty in another area only if the need in that area were so serious as to clearly require his services there.

Size.—The number of reserve officers to be appointed under the present program is limited. Ultimately the reserve is expected to be built up to approximately 5,000 officers—physicians, dentists, sanitary engineers, nurses and persons in allied health professions. At the present time, the program provides for 2,000 officers. The principal need at this stage is for physicians.

Eligibility.—To be eligible for appointment to the Commissioned Reserve, a person must be an American citizen at least twenty-one years old and must have a professional degree. A person need not have had experience in the public health field to be eligible. Grades in the Commissioned Reserve correspond to the grades in the regular Commissioned Corps of the Public Health Service and to grades in the Army, Navy, and Air Force. The grade to which an officer is appointed is determined by his years of education, training and experience.

Duration of Appointments.—All Reserve Corps commissions in the Public Health Service are for periods of five years. They are made by the Secretary of Health, Education, and Welfare, and are renewable at the end of each five-year period. If the officers is reappointed, his grade is determined by the level of his training and experience at that time. An officer can resign his commission at any time.

Training Program.—The Service will make every effort to train officers of the Commissioned Reserve in present-day emergency health problems, particularly those associated with atomic, biological and chemical warfare. Insofar as funds permit, officers of the Commissioned Reserve will be given opportunities to go on active duty for limited periods for training purposes.

The Service also will offer opportunities for training not involving active duty. As the reserve is built up to emergency strength, a variety of training methods will be employed. The aim is that every officer of the reserve will receive some basic training in emergency health problems. Intensive, specialized training is planned for a limited number of reserve officers.

Appointments.—The first step toward obtaining a commission as a reserve officer of the Public Health Service is to submit an application on a form provided by the Service.

Filling out this application obligates neither the applicant nor the Service. It does, however, provide the Service with the necessary information on which to determine whether the applicant is eligible and, if eligible, to what grade he should be appointed. If the applicant is judged eligible, he will be informed of the next step.

General Considerations.—No one can know in advance what he will be doing if a grave national emergency develops. But one thing is certain: Everyone with training and experience in health professions will be needed in a dozen places at once.

Obviously, we must anticipate as many of the problems as we can, get ready to deal with them in the most realistic way possible and stay ready.

In any successful attack, treatment and care of the injured will be a monumental task, but it will be only part of the problem. Those who escape direct injury will be the human resources we have left. Their health will have to be safeguarded at all costs.

Even in emergencies resulting from natural causes, health personnel are often spread too thin or are not readily available.

In an attack, these problems would breed and multiply—not in days and weeks but in hours and minutes.

There must be provision for physicians, en-

Reports and Announcements

MEDICAL MEETINGS

National

American Association of Blood Banks, eighth annual meeting, Palmer House, Chicago, Illinois, November 19-21, 1955.

International

International College of Surgeons, Cape Cod regional meeting, Chatham Bars Inn, Chatham, Massachusetts, July 1-4, 1955.

International Symposium on Enzymes: Units of Biological Structure and Function, Henry Ford Hospital, Detroit, Michigan, November 1-3, 1955.

AMERICAN BOARD OF OBSTETRICS AND GYNECOLOGY

Applications for certification for the 1956 Part I examinations are now being accepted by the American Board of Obstetrics and Gynecology. Candidates are urged to make application as early as possible—before October 1, 1955.

Information can be obtained from the secretary of the board, Dr. Robert L. Faulkner, 2105 Adelbert Road, Cleveland 6, Ohio.

MINNESOTA SYMPOSIUM ON ARTERIOSCLEROSIS

The Minnesota Symposium on Arteriosclerosis, sponsored by the University of Minnesota and the Minnesota Heart Association, will be held at the Mayo Memorial, University of Minnesota Medical School, Minneapolis, on September 7, 8 and 9, 1955.

Five general sessions and a half-day of clinic and laboratory visits will be devoted to five major topics: "The Challenge of Arteriosclerosis," "Atherosclerosis," "Peripheral and Cerebral Arteriosclerosis," "The Internist and Some Tools," and "The Surgical Treatment of Arteriosclerosis."

In addition to Minnesota speakers, guest lecturers will include representatives from other U. S. medical centers and from South Africa, Sweden, Canada, Scotland, Italy and Germany. Principal speaker at a dinner meeting at the Minneapolis Club on September 7 will be Dr. Paul Dudley White, Boston, who will discuss "The Coronaries Through the Ages."

General chairman of the symposium is Dr. Ancel Keys of the University of Minnesota. For further information, reservations, housing, et cetera, write Dr. Robert B. Howard, Mayo Memorial, University of Minnesota, Minneapolis 14, Minnesota.

ASSEMBLY IN OTOLARYNGOLOGY

The Department of Otolaryngology, University of Illinois College of Medicine, announces its annual Assembly in Otolaryngology from September 19 through October 1. This assembly will consist of two parts.

Part 1, September 19-24, will be devoted to surgical anatomy of the head and neck, fundamental principles of neck surgery and histopathology of the ear, nose and throat. This week will be under the personal direction of Dr. Maurice F. Snitman. Part 2, September 26-October 1, will be devoted entirely to lectures and panel discussion of advancements in otolaryngology. The chairman of this section will be Dr. Emanuel M. Skolnik.

Registration is optional for one or both weeks.

WORLD MEDICAL ASSOCIATION JOURNALISM MEETING

The sixth medical journalism meeting, sponsored by the World Medical Association, will be held in connection with the association's ninth General Assembly in Vienna, Austria, September 20 to 26, 1955. September 23 will be devoted to the medical journalism program, at which the main topic will be "Problems of Teutonic Medical Publications."

Editors of medical journals are invited to attend. A complete program will be sent on request. For further information, write the World Medical Association, 345 East 46th Street, New York 17, N. Y.

INDUSTRIAL MEDICINE COURSE

A full-time eight-week comprehensive course in industrial medicine for physicians will be given in the Post-Graduate Medical School of New York University-Bellevue Medical Center commencing Monday, September 26, 1955.

Among the subjects being offered to physicians are: organization, administration and economics of an industrial medical department, the practice of preventive and constructive medicine in industry, the clinical aspects of occupational diseases, industrial injuries and the elements of safety programs, toxicology and industrial hygiene for the physician. Opportunities will be provided for attendance at medical, surgical and clinical pathological conferences during the course.

Applications should be sent to the Dean, NYU Post-Graduate Medical School, New York 16, N. Y. Tuition is $250.

IATROGENIC HEART DISEASE

(Continued from Page 442)

On examination, her heart action was quiet, easy and regular at 80 beats per minute and her blood pressure, which was 170 on first reclining, settled down to 136/70.

Summary

This case history is typical of a woman who was badly frightened when the doctor told her she had serious heart disease and advised her to be careful.

Even though no serious heart disease was found, she continued to be fearful and needed repeated examinations and reassurance to keep her going.

Woman's Auxiliary

RAMSEY AUXILIARY ELECTS OFFICERS

Mrs. L. T. Simons

The regular luncheon meeting of the Woman's Auxiliary to the Ramsey County Medical Society was held on April 25, 1955, in the Commodore Hotel. Members accepted the slate of officers presented by the nominating committee, of which Mrs. Harvey O. Beek was chairman. Officers for the coming year are:

President	Mrs. H. O. Peterson
President-Elect	Mrs. C. W. Froats
First Vice President	Mrs. Rodney F. Sturley
Second Vice President	Mrs. H. J. Wolff
Third Vice President	Mrs. A. E. Ritt
Recording Secretary	Mrs. J. P. Medelman
Corresponding Secretary	Mrs. S. M. Loken
Treasurer	Mrs. O. I. Sohlberg

Mrs. W. P. Gardner, retiring president, called a board meeting on May 2. Committee reports were given.

Mrs. H. O. Peterson entertained eighteen new and prospective auxiliary members at a get-acquainted coffee party in her home on May 8. Interests and hobbies were discussed.

The annual luncheon meeting was held on May 16 at the University Club. Mrs. W. P. Gardner announced the allocation of funds as approved by the members:

One gift of $500 to the American Medical Education Foundation, designated for the University of Minnesota.

Two gifts of $100 each to University of Minnesota medical students, subject to approval of the Dean of the Medical School.

One gift of $150 to the Hallie Q. Brown settlement house, $150 to the Neighborhood Settlement house to be used to send children to camp.

Mrs. Gardner introduced the new officers to the group and then presented the flower-bedecked gavel to Mrs. H. O. Peterson, who accepted her new responsibility very graciously. The auxiliary members gave a rising vote of thanks to Mrs. Gardner for her fine work during the past year.

Mrs. S. M. Loken, program chairman, presented Mr. Otto Dallman, sculptor, who gave a very interesting demonstration using plaster, granite and clay as media of expression.

In Memoriam

JOHN D. B. GALLOWAY

Dr. John D. B. Galloway, orthopedic surgeon of Minneapolis, died May 4, 1955. He was forty-seven years old.

Dr. Galloway was born in Lewistown, Pa. He attended Cornell University and received his medical degree from Temple University. In 1938, he received a degree of M.S. in orthopedic surgery at the University of Minnesota, having entered the Mayo Foundation as a fellow in orthopedic surgery in 1936.

From 1942 to 1946 Dr. Galloway served in the army. He was chief surgeon at Shriners' Hospital for Crippled Children and was a member of the staffs at Swedish and Lutheran Deaconess Hospitals and of the visiting staff at St. Barnabas hospital. He was attending orthopedic surgeon at General Hospital, Jones-Harrison home and Ebenezer home. He was a clinical assistant in orthopedic surgery at the University of Minnesota.

Dr. Galloway was a member of the American Academy of Orthopedic Surgeons, American College of Surgeons, American Medical Association, Minnesota State Medical Association, Hennepin County Medical Society, Clinical Orthopedic Society, International College of Surgeons and Minnesota Dakota Orthopedic Club. He was a diplomate of the American Board of Orthopedic Surgery.

Dr. Galloway was also a member of Sigma Chi and of St. Luke's Lutheran Church in St. Louis Park.

He is survived by his wife, Gertrude; his daughter, Jane, and his mother, Mrs. Willa B. Galloway, Chester, Pennsylvania.

WILLIAM ANTHONY MILLER

Dr. William A. Miller, born in Appleton, Wisconsin, on July 30, 1872, died in New York Mills, Minnesota, June 1, 1955, after nearly sixty years in the medical profession.

Dr. Miller graduated from the Kansas City Medical College in 1896. He then went to New York Mills and became an active member in many community activities. In February, 1953, a banquet was held by the Lions in New York Mills to honor Dr. Miller for his lifetime of service. He was a member of the school board and served on the Board of Health, as Deputy Coroner, as an examiner for selective service, and participated in many bond drives during both world wars.

He was a life member of the Minnesota State Medical Association, the American Medical Association and had been a member of the Park Region District and County Medical Society since its inception. He was on the staff of St. James Hospital in Perham.

Dr. Miller is survived by his wife, Jessie; a sister, Mrs. F. G. Brabec, Perham; a son, Maurice, New York Mills; two daughters, Mrs. Oscar A. Carlson and Mrs. Eino Kyllonen, both of Minneapolis, and six grandchildren.

Of General Interest

The award of merit of the Ohio Valley Proctologic Society has been given to **Dr. Louis A. Buie,** senior consultant in the section of proctology at the Mayo Clinic, Rochester. The award was made during the recent annual meeting of the American Proctologic Society in New York City.

* * *

Dr. Merrill D. Chesler, Minneapolis, was the principal speaker at a meeting of the Blue Earth Valley Medical Society at Madelia on May 19. He discussed "Burns—Skin Grafts and Flaps" in regard to plastic and reconstructive surgery.

* * *

Dr. J. A. Abullarade, Cokato, staff member of the Cokato Hospital since November, 1954, reported on May 8 at Fort Sam Houston, San Antonio, Texas, for service in the armed forces. He entered the Army as a captain in the medical corps.
